Minimization Principles for the Linear Response Eigenvalue Problem I: Theory

Zhaojun Bai∗ Ren-Cang Li †

June 28, 2011

Abstract

We present two theoretical results for the linear response eigenvalue problem. The first result is a minimization principle for the sum of the smallest few positive eigenvalues. The second result is a couple of Cauchy-like interlacing inequalities. Although the linear response eigenvalue problem is a nonsymmetric eigenvalue problem, these results mirror the well-known Courant-Fischer trace minimization principle and Cauchy interlacing inequalities for the symmetric eigenvalue problem.

Key words and phrases. eigenvalue, eigenvector, minimization principle, random phase approximation, quantum linear response.

1 Introduction

In this paper, we consider the eigenvalue problem of the form:

\[ H z = \begin{bmatrix} 0 & K \\ M & 0 \end{bmatrix} \begin{bmatrix} y \\ x \end{bmatrix} = \lambda \begin{bmatrix} y \\ x \end{bmatrix} \equiv \lambda z, \quad (1.1) \]

where \( K \) and \( M \) are \( n \times n \) symmetric positive semi-definite matrices and one of them is definite. We refer to it as a linear response (LR) eigenvalue problem for the reason to be explained later. It can be seen that the eigenvalue problem (1.1) is equivalent to any one of the following product eigenvalue problems

\[ KM y = \lambda^2 y, \quad (1.2a) \]
\[ MK x = \lambda^2 x. \quad (1.2b) \]

Theoretically, if any one of them is solved, the solutions to the other two can be constructed from the solved one with little effort.

The LR eigenvalue problem (1.1) arises from computing excitation states (energies) of physical systems in the study of collective motion of many particle systems, ranging from silicon nanoparticles and nanoscale materials to analysis of interstellar clouds (see for example [5, 11, 15]). In computational quantum chemistry and physics, the excitation states are described by the random phase approximation (RPA), a linear response perturbation analysis in

the time-dependent Hartree-Fock and time-dependent density function theories. There are a
great deal of recent work and interests in developing efficient numerical algorithms and simula-
tion techniques for excitation response calculations of molecules for materials design in energy
science [7, 19, 20, 12].

The heart of (nonrelativistic) RPA calculation is to compute a few smallest positive eigen-
values and their corresponding eigenvectors of the following eigenvalue problem

$$\begin{pmatrix} A & B \\ -B & -A \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} = \lambda \begin{pmatrix} u \\ v \end{pmatrix},$$

(1.3)

where $A$ and $B$ are $n \times n$ real symmetric matrices such that the symmetric matrix
$$\begin{pmatrix} A & B \\ B & A \end{pmatrix}$$
is positive definite$^1$ [18, 23]. In physics and chemistry literature, it is this eigenvalue problem
that is referred to as the LR eigenvalue problem (see, e.g., [14]), or the RPA eigenvalue problem
(see e.g., [6, 22, 11]). The eigenvalue problem (1.3) is also a special case of the Hamiltonian
eigenvalue problem (see, e.g., [2, 3, 27]) because the matrix in (1.3) is a Hamiltonian matrix.

Define the symmetric orthogonal matrix

$$J = \frac{1}{\sqrt{2}} \begin{pmatrix} I_n & I_n \\ I_n & -I_n \end{pmatrix},$$

(1.4)

where $I_n$ is the $n \times n$ identity matrix. It can be verified that $J^T J = J^2 = I_{2n}$ and

$$J^T \begin{pmatrix} A & B \\ -B & -A \end{pmatrix} J = \begin{pmatrix} 0 & A - B \\ A + B & 0 \end{pmatrix},$$

(1.5)

which is $H$ in (1.1) with

$$K = A - B, \quad M = A + B.$$ 

(1.6)

Hence the Hamiltonian matrix in (1.3) and the matrix $H$ in (1.1) with (1.6) are similar through
$J$, making it equivalent to solve the eigenvalue problem for one by the one for the other. In fact,
both have the same eigenvalues with corresponding eigenvectors related by

$$\begin{pmatrix} y \\ x \end{pmatrix} = J^T \begin{pmatrix} u \\ v \end{pmatrix}, \quad \begin{pmatrix} u \\ v \end{pmatrix} = J \begin{pmatrix} y \\ x \end{pmatrix}.$$ 

(1.7)

Furthermore, the positive definiteness of the matrix $\begin{pmatrix} A & B \\ B & A \end{pmatrix}$ is equivalent to that both of $K$ and $M$ are positive definite since

$$J^T \begin{pmatrix} A & B \\ B & A \end{pmatrix} J = \begin{pmatrix} A + B & 0 \\ 0 & A - B \end{pmatrix}.$$ 

(1.8)

By the equivalence of the eigenvalue problems (1.3) and (1.1), in this paper, we also refer to the
eigenvalue problem (1.1) as the linear response eigenvalue problem.

When both $K$ and $M$ are symmetric positive definite, as in the case for RPA [17, 24, 26], it
can be shown that the Hamiltonian matrix in (1.3) and thus the matrix $H$ in (1.1) have only
nonzero real eigenvalues and their nonzero eigenvalues come in $\pm \lambda$ pairs (see section 2). In
this case, Thouless [24] showed that the smallest positive eigenvalue $\lambda_{\text{min}}$ admits the following
minimization principle:

$$\lambda_{\text{min}} = \min_{u, v} \rho(u, v),$$

(1.9)

$^1$In this article we will focus on very much this case, except that the eigenvalue 0 is allowed, i.e., (1.3) has only
real eigenvalues.
where \( \varrho(u, v) \) is defined by
\[
\varrho(u, v) = \frac{(u^T v) \begin{pmatrix} A & B \\ B & A \end{pmatrix} (u^T v)}{|u^T u - v^T v|},
\]
and the minimization is taken among all vectors \( u, v \) such that \( u^T u - v^T v \neq 0 \). By the similarity transformation (1.5) and using the relationships in (1.7), we have
\[
\varrho(u, v) \equiv \rho(x, y) \defeq x^T K x + y^T M y \frac{|x^T y|}{2|x^T y|},
\]
and thus equivalently [26]
\[
\lambda_{\min} = \min_{x, y \in \mathbb{D}} \rho(x, y),
\]
where the domain \( \mathbb{D} \) consists of all \( x \) and \( y \) such that either \( x^T y \neq 0 \) or \( x^T y = 0 \) but \( x^T K x + y^T M y > 0 \). This removes those \( x \) and \( y \) that annihilate both the numerator and the denominator from the domain. In particular \( x = y = 0 \) is not in the domain \( \mathbb{D} \).

We will refer to both \( \varrho(u, v) \) and \( \rho(x, y) \) as the Thouless functionals but in different forms. Although \( \varrho(u, v) \equiv \rho(x, y) \) under (1.7), in this paper we primarily work with \( \rho(x, y) \) to develop extensions of (1.12) and efficient numerical methods.

The theoretical part of our contributions in this paper are three-folds:

1. We extended the minimization principle (1.12) to include the case when one of \( K \) and \( M \) is singular and thus \( \lambda_{\min} = 0 \) for which “min” needs to be replaced by “inf”.
2. We introduced and proved a subspace version of the minimization principle (1.9):
\[
\sum_{i=1}^{k} \lambda_i = \frac{1}{2} \min_{U, V \in \mathbb{R}^{n \times k}} \frac{\text{trace}(U^T K U + V^T M V),}{U^T V = I_k}
\]
where \( \lambda_i (1 \leq i \leq k) \) are the first \( k \) smallest positive eigenvalues\(^2\) of \( H \), and \( U, V \in \mathbb{R}^{n \times k} \). Moreover, “inf” can be replaced by “min” if both \( K \) and \( M \) are definite.

Equation (1.13) suggests that
\[
\frac{1}{2} \text{trace}(U^T K U + V^T M V) \quad \text{subject to } U, V \in \mathbb{R}^{n \times k} \text{ and } U^T V = I_k
\]
is a proper subspace version of the Thouless functional in the form of \( \rho(\cdot, \cdot) \). By exploiting the close relation through (1.7) between \( \rho \) and \( \varrho \), we also obtained a subspace version of the minimization principle (1.9) in Theorem 3.3 for the original LR eigenvalue problem (1.3) and, at the same time, a proper subspace version of the Thouless functional in the form of \( \varrho(\cdot, \cdot) \).

3. We proved that the \( i \)th positive eigenvalue of a structure-preserving projection matrix \( H_{SR} \) of \( H \) onto a pair of subspaces is no smaller than the corresponding \( \lambda_i \) of \( H \). In many ways, \( H_{SR} \) plays the same role for the LR eigenvalue problem (1.1) as the Rayleigh quotient matrix for the symmetric eigenvalue problem [16].

\(^2\)\( H \) has an even number of eigenvalue 0 if any. For convenience, the plus sign is artificially assigned to half of the 0s and the negative sign to the other half. Although +0 = −0 in value, we regard +0 as positive. Doing so allows us to say that \( H \) has \( n \) positive eigenvalues and \( n \) negative eigenvalues without causing any ambiguity.
These theoretical contributions mirror the well-known results for the symmetric eigenvalue problem, namely the minimization principle of the Rayleigh quotient, the trace minimization, and Cauchy interlacing inequalities, see for examples [10, 16, 21].

This is the first paper of ours in a sequel of two. Here we focus on treating the theoretical aspect of the LR eigenvalue problem. The numerical aspect will be the subject of study in the second paper [1]. The rest of this paper is organized as follows. In section 2, we review basic theoretical results about the eigenvalue problem (1.1) and then introduce the concept of a pair of deflating subspaces and its approximation properties. In section 3, we extend the minimization principle (1.12) by Thouless and Tsiper to include several eigenvalues and present our Cauchy-like interlacing inequalities and more. We will also discuss the metric about the best approximation from a pair of approximate deflating subspaces. For simplicity of exposition, most proofs are deferred to appendix A. Concluding remarks are in section 4.

Throughout this paper, \( \mathbb{R}^{n \times m} \) is the set of all \( n \times m \) real matrices, \( \mathbb{R}^n = \mathbb{R}^{n \times 1} \), and \( \mathbb{R}^1 \). \( I_n \) (or simply \( I \) if its dimension is clear from the context) is the \( n \times n \) identity matrix, and \( e_j \) is its \( j \)th column. The superscript \( \cdot^T \) takes transpose only. We shall also adopt MATLAB-like convention to access the entries of vectors and matrices. \( i : j \) is the set of integers from \( i \) to \( j \) inclusive. For a vector \( u \) and a matrix \( X \), \( u(j) \) is \( u \)'s \( j \)th entry, \( X(i,j) \) is \( X \)'s \((i,j)\)th entry; \( X \)'s submatrices \( X_{(k_1:j_1,i_1:j_1)} \), \( X_{(k_2:j_2,i_1:j_2)} \), and \( X_{(i_1:j_1)} \) consist of intersections of row \( k \) to row \( \ell \) and column \( i \) to column \( j \), row \( k \) to row \( \ell \), and column \( i \) to column \( j \), respectively. If \( X \) is nonsingular, \( \kappa(X) \equiv \|X\|_2\|X^{-1}\|_2 \) is its spectral condition number, where \( \| \cdot \|_2 \) denotes the \( \ell_2 \)-norm of a vector or the spectral norm of a matrix. For matrices or scalars \( X_i \), both \( \text{diag}(X_1, \ldots, X_k) \) and \( X_1 \oplus \cdots \oplus X_k \) denote the same matrix

\[
\begin{pmatrix}
X_1 \\
\vdots \\
X_k
\end{pmatrix}
\]

The assignments in (1.1) will be assumed, namely \( H \) is always defined that way for given \( K, M \in \mathbb{R}^{n \times n} \) which are assumed by default to be symmetric positive semi-definite and one of which is definite, unless explicitly stated differently. This assumption is essential to our main contributions in this paper and its following one [1], although a few results do not require this. We will point them out along the way.

## 2 Basic theory and pair of deflating subspaces

### 2.1 Basic theory

In this subsection, we discuss some basic theoretical results on the eigenvalue problem (1.1). Most results are likely known, but cannot be found in one place. They are collected here for the convenience of our later developments. As discussed in section 1, the eigenvalue problem (1.1) of \( H \) and the eigenvalue problems (1.2) of \( KM \) and \( MK \) are all equivalent in the sense that if any one of them is solved, the solutions to the other two can be constructed from the solved one with little effort. Detail is given in Theorem 2.1 below.

**Theorem 2.1.** 1. If \( \lambda \) is an eigenvalue of \( H \) and (1.1) holds for \( z \neq 0 \), then equations in (1.2) hold, and \( \lambda^2 \) is an eigenvalue of \( KM \) if \( y \neq 0 \) and \( \lambda^2 \) is an eigenvalue of \( MK \) if \( x \neq 0 \). In particular if \( \lambda \neq 0 \), then both \( x \neq 0 \) and \( y \neq 0 \) and thus \( \lambda^2 \) is an eigenvalue of both \( KM \) and \( MK \).
2. Equation (1.2a) with \( y \neq 0 \) implies (1.1) for the nonzero \( z \) defined by
\[
z = \begin{cases} 
  \left( \begin{array}{c} y \\ \lambda^{-1}My \end{array} \right), & \text{if } \lambda \neq 0, \\
  \left( \begin{array}{c} y \\ 0 \end{array} \right), & \text{if } \lambda = 0 \text{ and } My = 0, \\
  \left( \begin{array}{c} 0 \\ My \end{array} \right), & \text{if } \lambda = 0 \text{ and } My \neq 0.
\end{cases}
\]

3. Equation (1.2b) with \( x \neq 0 \) implies (1.1) for the nonzero \( z \) defined by
\[
z = \begin{cases} 
  \left( \begin{array}{c} \lambda^{-1}Kx \\ x \end{array} \right), & \text{if } \lambda \neq 0, \\
  \left( \begin{array}{c} 0 \\ x \end{array} \right), & \text{if } \lambda = 0 \text{ and } Kx = 0, \\
  \left( \begin{array}{c} Kx \\ 0 \end{array} \right), & \text{if } \lambda = 0 \text{ and } Kx \neq 0.
\end{cases}
\]

4. Each nonzero \( \mu = \lambda^2 \) as an eigenvalue of \( KM \) (and \( MK \)) leads to two distinct eigenvalues of \( H \) and two corresponding eigenvectors \( z \).

5. The number of zero eigenvalues of \( H \) is twice as many as the number of zero eigenvalues of \( KM \) (or \( MK \)).

**Proof.** We note that (1.1) is equivalent to
\[
Kx = \lambda y, \quad My = \lambda x. \tag{2.1}
\]

1. Only the part for \( \lambda \neq 0 \) needs a proof. For that, it suffices to show if \( \lambda \neq 0 \), then both \( x \neq 0 \) and \( y \neq 0 \). Suppose to the contrary that \( \lambda \neq 0 \) and \( y = 0 \). Then \( x \neq 0 \) since either \( x \) or \( y \) or both must not be zero. \( Kx = 0 \) by (2.1), and thus \( \lambda^2 x = 0 \Rightarrow \lambda = 0 \) or \( x = 0 \) by (1.2b), a contradiction. Similarly \( \lambda \neq 0 \) and \( x = 0 \) cannot happen either.

2. and 3. can be verified straightforwardly.

4. For each \( \mu = \lambda^2 \neq 0 \), there are two distinct square roots \( \lambda \)'s which yield two nonzero \( z \)'s in 2. and 3. as corresponding eigenvectors.

5. It is well-known that \( KM \) and \( MK \) have the same eigenvalues. Since \( H \) and \( H^2 \) have the same number of zero eigenvalues and
\[
H^2 = \begin{pmatrix} KM & 0 \\ 0 & MK \end{pmatrix},
\]
the conclusion follows.

**Remark 2.1.** Our implicit assumption that \( K \) and \( M \) are real and symmetric positive semi-definite and one of them is definite is not used in the proof. Thus Theorem 2.1 is actually valid for all square matrices \( K \) and \( M \).
Suppose that $K$ and $M$ are symmetric positive semi-definite. Since $KM = K^{1/2}K^{1/2}M$ has the same eigenvalues as $K^{1/2}MK^{1/2}$ which is also symmetric positive semi-definite, all eigenvalues of $KM$ are real and nonnegative. Denote these eigenvalues by $\lambda_i^2$ ($1 \leq i \leq n$) in ascending order, i.e.,

$$0 \leq \lambda_1^2 \leq \lambda_2^2 \leq \cdots \leq \lambda_n^2,$$

(2.2)

where all $\lambda_i \geq 0$ and thus $0 \leq \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n$. The eigenvalues of $MK$ are $\lambda_i^2$ ($1 \leq i \leq n$), too. Theorem 2.1 implies the eigenvalues of $H$ are

$$\pm \lambda_i \quad \text{for } i = 1, 2, \ldots, n.$$  

(2.3)

An immediate consequence of this is that the eigenvalues of $H$ come in $\pm \lambda$ pairs. In particular, it has an even number of zero eigenvalues. As we mentioned in the footnote 2, for convenience, we shall associate half of 0 eigenvalues with the positive sign and the other half with the negative sign. Although $+0 = -0$ in value, we regard $+0$ as positive and doing so legitimizes the use of the phrase “the first $k$ smallest positive eigenvalues of $H$” to refer to $\lambda_i$ for $1 \leq i \leq k$ without ambiguity even when $\lambda_1 = +0$. Throughout this paper, we will use $\lambda_i^2$ ($1 \leq i \leq n$) in ascending order as in (2.2) to denote the eigenvalues of $KM$.

Set

$$\mathcal{J} = \begin{pmatrix} 0 & I_n \\ I_n & 0 \end{pmatrix},$$  

(2.4)

which is symmetric but indefinite. The matrix $\mathcal{J}$ induces an indefinite inner product on $\mathbb{R}^{2n}$:

$$\langle z_1, z_2 \rangle_{\mathcal{J}} \overset{\text{def}}{=} z_1^T \mathcal{J} z_2.$$

The following theorem tells us some orthogonality properties among the eigenvectors of $H$. It does not require that one of $K$ and $M$ are definite.

**Theorem 2.2.** Suppose $K$ and $M$ are symmetric and positive semi-definite.

1. Let $(\lambda, z)$ be an eigenpair of $H$, i.e., $Hz = \lambda z$ and $z = \begin{pmatrix} y \\ x \end{pmatrix} \neq 0$, where $x, y \in \mathbb{R}^n$. Then $\lambda \langle z, z \rangle_{\mathcal{J}} = 2\lambda x^T y > 0$ if $\lambda \neq 0$. In particular, this implies $\langle z, z \rangle_{\mathcal{J}} = 2x^T y \neq 0$ if $\lambda \neq 0$.

2. Let $(\alpha_i, z_i)$ ($i = 1, 2$) be two eigenpairs of $H$. Partition $z_i = \begin{pmatrix} y_i \\ x_i \end{pmatrix} \neq 0$, where $x_i, y_i \in \mathbb{R}^n$.

   (a) If $\alpha_1 \neq \alpha_2$, then $\langle z_1, z_2 \rangle_{\mathcal{J}} = y_1^T x_2 + x_1^T y_2 = 0$.

   (b) If $\alpha_1 \neq \pm \alpha_2 \neq 0$, then $y_1^T x_2 = x_1^T y_2 = 0$.

**Proof.** 1. $Hz = \lambda z$ gives $Kx = \lambda y$ and $My = \lambda x$. We then have $x^T Kx = \lambda x^T y$ and $y^T My = \lambda y^T x$. So $\lambda x^T y \geq 0$. It suffices to show $x^T y \neq 0$ if $\lambda \neq 0$. Suppose to the contrary that $\lambda \neq 0$ but $x^T y = 0$. Then

$$x^T y = 0 \Rightarrow x^T Kx = x^T y \neq 0 \Rightarrow Kx = My = 0 \Rightarrow \lambda y = \lambda x = 0 \Rightarrow x = y = 0,$$

contradicting $z \neq 0$.

2. Since

$$\mathcal{J} H = \begin{pmatrix} M & 0 \\ 0 & K \end{pmatrix} = (\mathcal{J} H)^T$$

is symmetric and positive semi-definite, we have

$$\alpha_2 z_1^T \mathcal{J} z_2 = z_1^T (H z_2) = z_1^T (\mathcal{J} H) z_2 = z_1^T (\mathcal{J} H)^T z_2 = (H z_1)^T \mathcal{J} z_2 = \alpha_1 z_1^T \mathcal{J} z_2,$$
and therefore \((\alpha_2 - \alpha_1)z_1^Tz_2 = 0\), which implies that \(z_1^Tz_2 = 0\) if \(\alpha_1 \neq \alpha_2\). Suppose that \(\alpha_1 \neq \pm \alpha_2\). Note that \(-\alpha_2\) is an eigenvalue of \(H\), too, with eigenvector \((-y_2 \ x_2)\). By what we just proved, we have
\[
y_1^Tx_2 + x_1^Ty_2 = 0, \quad y_1^Tz_2 + x_1^T(-y_2) = 0
\]
which yield \(y_1^Tx_2 = x_1^Ty_2 = 0\).

More can be said when one of \(K\) and \(M\) is definite. For the sake of presentation, we shall always either assume that \(M\) is definite or only provide proofs for definite \(M\) whenever one of \(K\) and \(M\) is required to be definite. Doing so loses no generality because the interchangeable roles played by \(K\) and \(M\) makes it rather straightforward to create a version for the case when \(K\) is definite by simply swapping \(K\) and \(M\) in each of their appearances. The following theorem is critical to our theoretical developments.

**Theorem 2.3.** Suppose that \(M\) is definite. Then the following statements are true:

1. There exists a nonsingular \(Y \in \mathbb{R}^{n \times n}\) such that
   \[
   K = Y \Lambda^2 Y^T, \quad M = XX^T,
   \]
   where \(\Lambda = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)\) and \(X = Y^{-T}\).

2. If \(K\) is also definite, then all \(\lambda_i > 0\) and \(H\) is diagonalizable:
   \[
   H \begin{pmatrix} Y\Lambda & Y\Lambda \\ X & -X \end{pmatrix} = \begin{pmatrix} Y\Lambda & Y\Lambda \\ X & -X \end{pmatrix} \begin{pmatrix} \Lambda & 0 \\ 0 & -\Lambda \end{pmatrix}.
   \]

3. \(H\) is not diagonalizable if and only if \(\lambda_1 = 0\) which happens when and only when \(K\) is singular.

4. The \(i\)th column of \(Z = \begin{pmatrix} Y\Lambda \\ X \end{pmatrix}\) are the eigenvector corresponding to \(\lambda_i\) and it is unique if
   (a) \(\lambda_i\) is a simple eigenvalue of \(H\), or
   (b) \(i = 1, \lambda_1 = +0 < \lambda_2\). In this case, 0 is a double eigenvalue of \(H\) but there is only one eigenvector associated with it.

5. If \(0 = \lambda_1 = \cdots = \lambda_\ell < \lambda_{\ell+1}\), then \(H\)’s Jordan canonical form is
   \[
   \begin{pmatrix} 0 \ 0 \\ 1 \ 0 \end{pmatrix} \oplus \cdots \oplus \begin{pmatrix} 0 \ 0 \\ 1 \ 0 \end{pmatrix} \oplus \text{diag}(\lambda_{\ell+1}, -\lambda_{\ell+1}, \ldots, \lambda_n, -\lambda_n).
   \]
   Thus \(H\) has 0 as an eigenvalue of algebraic multiplicity \(2\ell\) with only \(\ell\) linear independent eigenvectors which are the columns of \(\begin{pmatrix} 0 \\ X_{(\cdot, 1: \ell)} \end{pmatrix}\).

6. The eigen-decompositions of \(KM\) and \(MK\) are
   \[
   (KM)Y = Y \Lambda^2, \quad (MK)X = X \Lambda^2,
   \]
   respectively.

7. The eigen-decomposition for the matrix pencil \(MKM - \lambda M\) is
   \[
   MKM = X \Lambda^2 X^T, \quad M = XX^T.
   \]
Proof. 1. Since $M^{-1}$ is symmetric and positive definite, it has a Cholesky decomposition $M^{-1} = R^T R$, where $R \in \mathbb{R}^{n \times n}$ is nonsingular. That $R^{-T} K R^{-1}$ is symmetric and positive semi-definite implies that it has the eigen-decomposition $R^{-T} K R^{-1} = Q \Lambda^2 Q^T$, where $Q \in \mathbb{R}^{n \times n}$ is orthogonal. Now take $Y = R^T Q$ to give (2.5).

2. Since $X = Y^{-T}$, we have from (2.5)

$$KX = YA^2, \quad MY = X.$$  \hfill (2.10)

Rewrite (2.10) as

$$KX = (YA) A, \quad M(YA) = XA,$$  \hfill (2.11)

which gives (2.6). It can be verified that $\begin{pmatrix} YA & Y A \\
X & -X \end{pmatrix}$ is nonsingular if all $\lambda_i > 0$. So (2.6) implies that $H$ is diagonalizable when all $\lambda_i > 0$.

For items 3. to 5. we deduce from (2.10)

$$H \begin{pmatrix} Y \\ X \end{pmatrix} = \begin{pmatrix} Y \\ X \end{pmatrix} \begin{pmatrix} \Lambda^2 \\ I_n \end{pmatrix}.$$  \hfill (2.12)

Since $\begin{pmatrix} Y \\ X \end{pmatrix}$ is always nonsingular, it suffices to investigate the same issues for $\begin{pmatrix} I_n \\ \Lambda^2 \end{pmatrix}$. With the so-called perfect shuffle, we have

$$P^T \begin{pmatrix} I_n \\ \Lambda^2 \end{pmatrix} P = \begin{pmatrix} \lambda_1^2 \\ 1 \end{pmatrix} \oplus \begin{pmatrix} \lambda_2^2 \\ 1 \end{pmatrix} \oplus \cdots \oplus \begin{pmatrix} \lambda_n^2 \\ 1 \end{pmatrix},$$

where $P = (e_1, e_{n+1}, e_2, e_{n+2}, \ldots, e_n, e_{2n})$. The eigenvalues of each 2-by-2 matrix

$$\begin{pmatrix} \lambda_i^2 \\ 1 \end{pmatrix}$$

are $\pm \lambda_i$, and such a matrix is diagonalizable if and only if $\lambda_i \neq 0$:

$$\begin{pmatrix} \lambda_i^2 \\ 1 \end{pmatrix} \begin{pmatrix} \lambda_i & \lambda_i \\
1 & -1 \end{pmatrix} = \begin{pmatrix} \lambda_i & \lambda_i \\
1 & -1 \end{pmatrix} \begin{pmatrix} \lambda_i & \lambda_i \\
-\lambda_i & \lambda_i \end{pmatrix}.$$ 

Therefore $H$ is not diagonalizable if and only if $\lambda_1 = 0$.

The verifications of items 6. and 7. are rather straightforward. \hfill \Box

We note that Jordan canonical form of the matrix $H$ in the previous theorem is a special case of the canonical forms of doubly structured matrices in the work of Mehl, Mehrmann and Xu [13].

### 2.2 Pair of deflating subspaces

Let $\mathcal{U}, \mathcal{V} \subseteq \mathbb{R}^n$ be subspaces. We call $\{\mathcal{U}, \mathcal{V}\}$ a pair of deflating subspaces of $\{K, M\}$ if

$$K \mathcal{U} \subseteq \mathcal{V} \quad \text{and} \quad M \mathcal{V} \subseteq \mathcal{U}.$$  \hfill (2.13)

Let $U \in \mathbb{R}^{n \times k}$ and $V \in \mathbb{R}^{n \times \ell}$ be the basis matrices for the subspaces $\mathcal{U}$ and $\mathcal{V}$, respectively, where $\dim(\mathcal{U}) = k$ and $\dim(\mathcal{V}) = \ell$. Then (2.13) implies that there exist $K_R \in \mathbb{R}^{k \times k}$ and $M_R \in \mathbb{R}^{k \times \ell}$ such that

$$K U = V K_R, \quad M V = U M_R.$$  \hfill (2.14)

Given \( U \) and \( V \), both \( K_R \) and \( M_R \) are uniquely determined by respective equations in (2.14), but there are numerous ways to express them. In fact for any left generalized inverses \( U^\dagger \) and \( V^\dagger \) of \( U \) and \( V \), respectively, i.e., \( U^\dagger U = I_k \) and \( V^\dagger V = I_\ell \),

\[
K_R = V^\dagger KU, \quad M_R = U^\dagger M V. \tag{2.15}
\]

There are infinitely many left generalized inverses \( U^\dagger \) and \( V^\dagger \). For example, two of them for \( U \) are

\[
U^\dagger = (U^T U)^{-1} U^T
\]
or

\[
U^\dagger = (V^T U)^{-1} V^T \quad \text{if } (V^T U)^{-1} \text{ exists.} \tag{2.16}
\]

But still \( K_R \) and \( M_R \) are unique. The second left generalized inverse (2.16) will become important later in preserving symmetry in \( K \) and \( M \).

Define

\[
H_R = \begin{pmatrix} 0 & K_R \\ M_R & 0 \end{pmatrix}.
\tag{2.17}
\]

Then \( H_R \) is the restriction of \( H \) onto \( V \oplus U \) with respect to the basis matrix \( V \oplus U \):

\[
\begin{pmatrix} 0 & K \\ M & 0 \end{pmatrix} \begin{pmatrix} V \\ U \end{pmatrix} = \begin{pmatrix} V \\ U \end{pmatrix} \begin{pmatrix} 0 & K_R \\ M_R & 0 \end{pmatrix}.
\tag{2.18}
\]

This also says that \( V \oplus U \) is an invariant subspace of \( H \). On the other hand, every invariant subspace of \( H \) yields a pair of deflating subspaces of \( \{ K, M \} \) as well.

**Theorem 2.4.**

1. If \( \{ U, V \} \) is a pair of deflating subspaces of \( \{ K, M \} \), then \( V \oplus U \) is an invariant subspace of \( H \).

2. Let \( Z \) be invariant subspace of \( H \) and let \( Z = \begin{pmatrix} V \\ U \end{pmatrix} \) be a basis matrix of \( Z \), where \( V \in \mathbb{R}^{n \times \ell} \).

Then \( \{ \text{span}(U), \text{span}(V) \} \) is a pair of deflating subspaces of \( \{ K, M \} \).

**Proof.** 1. That \( V \oplus U \) is an invariant subspace of \( H \) is a consequence of (2.18).

2. There is a matrix \( D \) such that \( HZ = ZD \) which leads to \( KU = VD \) and \( MV = UD \). Thus (2.13) holds for \( U = \text{span}(U) \) and \( V = \text{span}(V) \).

The following theorem says a subset of eigenvalues and eigenvectors of \( H \) can be recovered from those of \( H_R \).

**Theorem 2.5.** Let \( \{ U, V \} \) be a pair of deflating subspaces of \( \{ K, M \} \) and \( U \in \mathbb{R}^{n \times k} \) and \( V \in \mathbb{R}^{n \times \ell} \) be the basis matrices for the subspaces \( U \) and \( V \), respectively. Define \( K_R, M_R, \) and \( H_R \) by equations in (2.14) and (2.17). Then

\[
H_R \hat{z} = \begin{pmatrix} 0 & K_R \\ M_R & 0 \end{pmatrix} \begin{pmatrix} \hat{y} \\ \hat{x} \end{pmatrix} = \lambda \begin{pmatrix} \hat{y} \\ \hat{x} \end{pmatrix} \equiv \lambda \hat{z}
\]

implies (1.1) with \( x = U \hat{x} \) and \( y = V \hat{y} \), where \( \hat{z} = \begin{pmatrix} \hat{y} \\ \hat{x} \end{pmatrix} \) conformably partitioned.

**Proof.** \( H_R \hat{z} = \lambda \hat{z} \) yields \( K_R \hat{x} = \lambda \hat{y} \) and \( M_R \hat{y} = \lambda \hat{x} \). Therefore \( KU \hat{x} = VK_R \hat{x} = \lambda V \hat{y} \) and \( MV \hat{y} = UM_R \hat{y} = \lambda U \hat{x} \), as was to be shown. \( \square \)
$H_{\text{sr}}$ in (2.17) inherits the block structure in $H$ in (1.1): zero blocks remain zero blocks. But when $K$ and $M$ are symmetric, as in the RPA case, in general $H_{\text{sr}}$ may lose the symmetry property in its off-diagonal blocks $K_{\text{sr}}$ and $M_{\text{sr}}$, not to mention positive semi-definiteness of $K$ and $M$. We propose a modification to $H_{\text{sr}}$ to overcome this potential loss, when $W \overset{\text{def}}{=} U^T V$ is nonsingular. Factorize $W = W_1^T W_2$, where $W_1$ and $W_2$ are nonsingular, and define

$$H_{\text{sr}} = \begin{pmatrix} 0 & W_1^{-T} U^T K U W_1^{-1} \\ W_2^{-T} V^T M V W_2^{-1} & 0 \end{pmatrix}. \tag{2.19}$$

Note $H_{\text{sr}}$ shares not only the block structure in $H$ but also the symmetry and semi-definiteness in its off-diagonal blocks. In defining $H_{\text{sr}}$ here, it is assumed that $U^T V$ is nonsingular. For this, we have the following lemma.

**Lemma 2.1.** Suppose that one of $K$ and $M$ is definite. Let $\{U, V\}$ be a pair of deflating subspaces of $\{K, M\}$ with $\dim(U) = \dim(V) = k$, and let $U \in \mathbb{R}^{n \times k}$ and $V \in \mathbb{R}^{n \times k}$ be the basis matrices of the subspaces $U$ and $V$, respectively. Then $U^T V$ is nonsingular.

**Proof.** Equations in (2.14) hold for some $K_{\text{r}}$ and $M_{\text{r}}$. Thus

$$U^T K U = U^T V K_{\text{r}}, \quad V^T M V = V^T U M_{\text{r}}. $$

Suppose that $M$ is definite. Then $V^T M V$ is definite and thus nonsingular; so $V^T U$ is nonsingular from the second equation. \hfill \square

**Theorem 2.6.** Let $\{U, V\}$ be a pair of deflating subspaces of $\{K, M\}$ and $U \in \mathbb{R}^{n \times k}$ and $V \in \mathbb{R}^{n \times l}$ be the basis matrices for the subspaces $U$ and $V$, respectively. Suppose that $W \overset{\text{def}}{=} U^T V$ is nonsingular and is factorized as $W = W_1^T W_2$ with both $W_1$ and $W_2$ being nonsingular, and define $H_{\text{sr}}$ by (2.19). Then $H_{\text{sr}}$ is the restriction of $H$ onto $\mathcal{V} \oplus \mathcal{U}$ with respect to the basis matrices $V W_2^{-1} \oplus U W_1^{-1}$:

$$H \begin{pmatrix} V W_2^{-1} \\ U W_1^{-1} \end{pmatrix} \left( \begin{pmatrix} V W_2^{-1} \\ U W_1^{-1} \end{pmatrix} \right)^{-1} = H_{\text{sr}}. \tag{2.20}$$

Consequently, $H_{\text{sr}} \hat{z} = \lambda \hat{z}$ implies (1.1) with $x = U W_1^{-1} \hat{x}$ and $y = V W_2^{-1} \hat{y}$, where $\hat{z} = \begin{pmatrix} \hat{y} \\ \hat{x} \end{pmatrix}$ conformably partitioned.

**Proof.** Equations in (2.14) hold for some $K_{\text{r}}$ and $M_{\text{r}}$. Thus

$$U^T K U = (U^T V) K_{\text{r}} = W_1^T W_2 K_{\text{r}} \quad \text{and} \quad V^T M V = (V^T U) M_{\text{r}} = W_2^T W_1 M_{\text{r}},$$

which gives

$$W_1^{-T} U^T K U W_1^{-1} = W_2 K_{\text{r}} W_1^{-1} \quad \text{and} \quad W_2^{-T} V^T M V W_2^{-1} = W_1 M_{\text{r}} W_2^{-1}. \tag{2.21}$$

Now by (2.14) and (2.21), we have the identity (2.20) since

$$K(U W_1^{-1}) = V K_{\text{r}} W_1^{-1} = (V W_2^{-1})(W_2 K_{\text{r}} W_1^{-1}) = (V W_2^{-1}) (W_1^{-T} U^T K U W_1^{-1}).$$

and

$$M(V W_2^{-1}) = U M_{\text{r}} W_2^{-1} = U W_1^{-1} (W_1 M_{\text{r}} W_2^{-1}) = (U W_1^{-1}) (W_2^{-T} V^T M V W_2^{-1}).$$

Finally, apply Theorem 2.5 to conclude the proof. \hfill \square
Equations in (2.21) imply that under the conditions of Theorem 2.6, \( H_R \) and \( H_{SR} \) are similar:

\[
H_{SR} = \left( \begin{array}{cc} 0 & W_2 K_1 W_1^{-1} \\ W_1 M_R W_2^{-1} & 0 \end{array} \right) = \left( \begin{array}{cc} W_2 & 0 \\ 0 & W_1 \end{array} \right) H_R \left( \begin{array}{cc} W_2 & 0 \\ 0 & W_1 \end{array} \right)^{-1},
\]

(2.22)

which is not at all obvious from (2.17) and (2.19).

A trivial pair of deflating subspaces \( \{U, V \} \) is when \( U = V = \mathbb{R}^n \). In particular, for \( U, V \in \mathbb{R}^{n \times n} \) satisfying \( U^T V = I_n \), matrices

\[
H = \left( \begin{array}{cc} 0 & K \\ M & 0 \end{array} \right) \quad \text{and} \quad \left( \begin{array}{cc} 0 & U^T K U \\ V^T M V & 0 \end{array} \right)
\]

(2.23)

have the same eigenvalues. In fact, the two matrices in (2.23) are similar because of (2.18) and for the current case

\[
\left( \begin{array}{cc} V \\ U \end{array} \right)^{-1} = \left( \begin{array}{cc} U^T \\ V^T \end{array} \right).
\]

**Remark 2.2.** For this subsection, our default assumption on \( K \) and \( M \) is not required, except for Lemma 2.1.

\[\Box\]

### 2.3 Invariance properties of \( H_{SR} \)

In the previous subsection, \( H_{SR} \) was introduced as a structure-preserving projection of \( H \) onto a pair of deflating subspaces \( \{U, V\} \). But its definition in (2.19) does not require \( \{U, V\} \) being a pair of deflating subspaces. In fact, it is well-defined so long as \( U^T V \) is nonsingular, where \( U, V \in \mathbb{R}^{n \times k} \) are the basis matrices of \( U \subset \mathbb{R}^n \) and \( V \subset \mathbb{R}^n \), respectively. This observation will become critically important in the second part of this paper [1] where \( H_{SR} \) is often defined for a pair of approximate deflating subspaces and will play the same role in the LR eigenvalue computation as the Rayleigh quotient matrix does for the symmetric eigenvalue problem.

As we just pointed out, we need the non-singularity assumption on \( U^T V \) to define \( H_{SR} \). We note that this assumption is independent of the freedom in choosing basis matrices. Now we present a necessary and sufficient condition in terms of canonical angles between subspaces for this assumption. Recall that the canonical angles between \( U \) and \( V \) are defined to be

\[
\arccos \sigma_i, \quad i = 1, 2, \ldots, k,
\]

where \( \sigma_i (1 \leq i \leq k) \) are the singular values of \( (U^T U)^{-1/2} U^T V (V^T V)^{-1/2} \) [21]. Furthermore, the angle \( \angle(U, V) \) between \( U \) and \( V \) is defined to be

\[
\angle(U, V) = \max_i \arccos(\sigma_i) = \arccos(\min_i \sigma_i).
\]

Note the canonical angles \( \arccos \sigma_i \) and the angle \( \angle(U, V) \) are independent of the choices of basis matrices [21].

**Lemma 2.2.** Let \( U, V \in \mathbb{R}^{n \times k} \) be basis matrices of \( U \subset \mathbb{R}^n \) and \( V \subset \mathbb{R}^n \), respectively.

1. \( U^T V \) is nonsingular if and only if \( \angle(U, V) < \pi/2 \).
2. If \( \angle(U, V) < \pi/2 \), then \( \mathbb{R}^n = U \oplus V^\perp = V \oplus U^\perp \), where \( U^\perp \) and \( V^\perp \) are the orthogonal complements of \( U \) and \( V \), respectively.

**Proof.** Use the notations in the definition of \( \angle(U, V) \) above. \( U^T V \) is nonsingular if and only if all \( 1 \geq \sigma_i > 0 \) which is equivalent to all \( \arccos(\sigma_i) < \pi/2 \). This proves item 1.
Suppose \( \angle(U, V) < \pi/2 \) and thus \( U^T V \) is nonsingular. Any \( x \in \mathbb{R}^n \) can be written as \( x = Px + (I - P)x \), where

\[
P = U(V^T U)^{-1}V^T.
\]

(2.24)

Evidently \( Px \in U \). It can be verified that \( V^T (I - P) = 0 \) which implies \( (I - P)x \in V^\perp \). Hence \( \mathbb{R}^n = U + V^\perp \). Furthermore, if \( x \in U \) and \( x \in V^\perp \), then

\[
x = U \hat{x}, \quad 0 = V^T x = V^T U \hat{x}
\]

which implies \( \hat{x} = 0 \) and so must \( x = 0 \) because \( V^T U \) is nonsingular. This proves \( \mathbb{R}^n = U \oplus V^\perp \).

Each \( H_{SR} \) always corresponds uniquely to two subspaces:

\[
U = \text{span}(U), \quad V = \text{span}(V)
\]

that satisfy \( \angle(U, V) < \pi/2 \). On the other hand, two subspaces \( U \) and \( V \) satisfying \( \angle(U, V) < \pi/2 \) lead to (infinitely) many \( H_{SR} \), due to the following two non-unique choices:

\[
\begin{align*}
1. & \text{ Factorization } W = W_1^T W_2 \text{ is not unique.} \\
2. & \text{ Basis matrices } U \text{ and } V \text{ are not unique.}
\end{align*}
\]

(2.25)

In the next theorem, we present two invariance properties of \( H_{SR} \) with respect to these two non-unique choices. The properties are important in speaking about eigenvalue and eigenvector approximations from a pair of approximate deflating subspaces in [1].

**Theorem 2.7.** Let \( U, V \subset \mathbb{R}^n \) be two subspaces of dimension \( k \) such that \( \angle(U, V) < \pi/2 \). We have the following invariance properties of \( H_{SR} \):

1. The eigenvalues of \( H_{SR} \) defined by (2.19) are invariant with respect to any of the non-uniqueness listed in (2.25);

2. For any invariant subspace \( \mathcal{E} \) of \( H_{SR} \), the subspace

\[
\left\{ \begin{pmatrix} VW_2^{-1} \\ UW_1^{-1} \end{pmatrix} \hat{z} : \hat{z} \in \mathcal{E} \right\}
\]

(2.26)

is invariant with respect to any of the non-uniqueness listed in (2.25). By which we mean for any two realizations \( H_{SR}^{(0)} \) and \( H_{SR}^{(1)} \) of \( H_{SR} \) and the subspace (2.26) obtained from an invariant subspace \( \mathcal{E}_0 \) of \( H_{SR}^{(0)} \), there exists an invariant subspace \( \mathcal{E}_1 \) of \( H_{SR}^{(1)} \) which produces the same subspace (2.26). In particular, if \( \mathcal{E} \) has dimension 1, this gives an invariance property on the eigenvectors of \( H_{SR} \).

**Proof.** We first show the invariant properties with respect to different factorizations \( W = W_1^T W_2 \). To this end, we note that \( H_1 \defeq H_{SR} \) with \( W = W_1^T W_2 \) and \( H_0 \defeq H_{SR} \) with \( W = I_k^T W \) are similar:

\[
\begin{pmatrix} W_1^{-T} \\ W_1 \end{pmatrix}^{-1} H_1 \begin{pmatrix} W_1^{-T} \\ W_1 \end{pmatrix} = \begin{pmatrix} W_1^T \\ W_1^{-1} \end{pmatrix} H_1 \begin{pmatrix} W_1^{-T} \\ W_1 \end{pmatrix} = H_0.
\]

Next we verify the invariant properties with respect to different choices of basis matrices. To this end, it suffices to verify the invariant properties under the following substitutions:

\[
UR \leftarrow U, \quad VS \leftarrow V, \quad W_1 R \leftarrow W_1, \quad W_2 S \leftarrow W_2,
\]

(2.27)
where $R, S \in \mathbb{R}^{k \times k}$ are nonsingular because we have just proved the properties with respect to different decompositions of $W$. The verification is straightforward because $H_{SR}$ and

$$
\begin{pmatrix}
VW_2^{-1} \\
UW_1^{-1}
\end{pmatrix}
$$

do not change under the substitutions (2.27).

\[\square\]

**Remark 2.3.** For this subsection, our default assumption on $K$ and $M$ is not required. \[\diamondsuit\]

3 Minimization principles and Cauchy-like interlacing inequalities

We recall three well-known results for a symmetric matrix $A \in \mathbb{R}^{n \times n}$. Denote by $\theta_i$ ($1 \leq i \leq n$) $A$’s eigenvalues in ascending order. The first well-known result is the following minimization principle for $A$’s smallest eigenvalue $\theta_1$:

$$
\theta_1 = \min_{x \neq 0} \frac{x^T Ax}{x^T x}.
$$

(3.1)

The trace (or subspace) version of (3.1), the second well-known result, is

$$
\sum_{i=1}^{k} \theta_i = \min_{U \in \mathbb{R}^{n \times k}, U^TU = I_{k}} \text{trace}(U^T AU).
$$

(3.2)

Furthermore, given any $U \in \mathbb{R}^{n \times k}$ such that $U^TU = I_{k}$, denote by $\mu_i$ ($1 \leq i \leq k$) the eigenvalues of the projection matrix $U^T AU$ in ascending order. We have Cauchy interlacing inequalities – the third well-known result:

$$
\theta_i \leq \mu_i \leq \theta_{i+n-k} \quad \text{for} \quad 1 \leq k.
$$

(3.3)

The proofs of these well-known theoretical results can be found, for example, in [4, 16, 21]. They are crucial to the establishment of efficient numerical methods for the symmetric eigenvalue problem, and largely responsible for why the symmetric eigenvalue problems are regarded as nice eigenvalue problems in a wide range of applications.

In this section, we establish analogs of these results mainly for the LR eigenvalue problem (1.1).

3.1 Minimization principles

Theorem 3.1 is an analog of the minimization principle (3.1) for the symmetric matrix $A$. It is essentially (1.12) due to Tsiper [25, 26] who deduced it from (1.9) due to Thouless [24], except we allow one of $K$ and $M$ to be singular. We note that Theorem 3.2 presents a subspace version of Theorem 3.1. Although Theorem 3.1 is a corollary of Theorem 3.2, we decide to give a short proof anyway because the proof of Theorem 3.2 is long and is deferred to appendix A.

**Theorem 3.1.** Suppose that one of $K$ and $M$ is definite. Then we have

$$
\lambda_1 = \inf_{x,y \in \mathcal{D}} \rho(x,y).
$$

(3.4)

Moreover, “inf” can be replaced by “min” if and only if both $K$ and $M$ are definite. When they are definite, the optimal argument pair $(x,y)$ gives rise to an eigenvector $z = \begin{pmatrix} y \\ x \end{pmatrix}$ of $H$ associated with $\lambda_1$. 

13
Proof. Note \( \rho(x, y) \geq 0 \) for any \( x \) and \( y \). If \( K \) is singular, then \( \lambda_1 = 0 \). Pick \( x \neq 0 \) such that \( Kx = 0 \). Then \( x^T Mx > 0 \) since one of \( K \) and \( M \) is assumed definite. We have

\[
\rho(x, \epsilon x) = |\epsilon| x^T Mx/(2|x^T x|) \to 0 \quad \text{as} \quad \epsilon \to 0.
\]

This is (3.4) for the case. We now show that “inf” cannot be replaced by “min”. Suppose there were \( x \) and \( y \) such that \( x^T y \neq 0 \) and \( \rho(x, y) = 0 \). We note that \( \rho(x, y) = 0 \) and \( x^T y \neq 0 \) imply \( x^T Kx = y^T My = 0 \) which in turn implies \( Kx = My = 0 \), contradicting that one of \( K \) and \( M \) is definite.

Suppose \( K \) and \( M \) are definite. Then \( \lambda_1 > 0 \) and Equations in (2.5) hold for some nonsingular \( Y \in \mathbb{R}^{n \times n} \) and \( X = Y^{-T} \). We have

\[
\min_{x, y} \frac{x^T Kx + y^T My}{2|x^T y|} = \min_{x, y} \frac{x^T Y A^2 Y^T x + y^T Y^{-T} Y^{-1} y}{2|x^T Y^{-1} y|}
\]

\[
= \min_{\tilde{x}, \tilde{y}} \frac{\tilde{x}^T \tilde{x} + \tilde{y}^T \tilde{y}}{2|\tilde{x}^T \tilde{y}|}
\]

\[
\geq \min_{\tilde{x}, \tilde{y}} \frac{2 \sum_i \lambda_i |\tilde{x}(i)\tilde{y}(i)|}{2 \sum_i |\tilde{x}(i)\tilde{y}(i)|}
\]

\[
\geq \lambda_1,
\]

where \( \tilde{x} = Y^T x \) and \( \tilde{y} = Y^{-1} y \). Suppose \( 0 < \lambda_1 = \cdots = \lambda_\ell < \lambda_{\ell+1} \leq \cdots \leq \lambda_n \). Both equality signs in (3.5) and (3.6) hold if and only if

\[
\tilde{x}(i)\lambda_i = \tilde{y}(i) \quad \text{for } 1 \leq i \leq n,
\]

\[
\tilde{x}(i) = \tilde{y}(i) = 0 \quad \text{for } \ell < i \leq n,
\]

i.e., \( \tilde{y} = \Lambda \tilde{x} \) and \( \tilde{x}_{(\ell+1:n)} = \tilde{y}_{(\ell+1:n)} = 0 \). So for their corresponding optimal argument pair \((x, y)\),

\[
Kx = KY^{-T} \tilde{x} = KX \tilde{x} = Y A^2 \tilde{x} = Y A \tilde{y} = \lambda_1 Y \tilde{y} = \lambda_1 y,
\]

and similarly \( My = \lambda_1 y \).

\[\Box\]

Remark 3.1. Equation (3.4) is actually true even both \( K \) and \( M \) are singular (but still positive semi-definite, of course). They are two cases.

1. Both \( K \) and \( M \) are singular and their kernels are not orthogonal to each other, i.e., there are nonzero vectors \( x \) and \( y \) such that \( Kx = My = 0 \) and \( x^T y \neq 0 \). For such a case, we have

\[
\lambda_1 = \min_{x, y} \rho(x, y).
\]

2. Both \( K \) and \( M \) are singular but their kernels are orthogonal to each other. For such a case, we have (3.4) but “inf” cannot be replaced by “min”. Here is why. Since \( K \) is singular, we pick \( x \neq 0 \) such that \( Kx = 0 \). Then \( Mx \neq 0 \) because the kernels of \( K \) and \( M \) are orthogonal to each other. So \( x^T M = (Mx)^T \neq 0 \) which says at least one of the columns of \( M \) is not orthogonal to \( x \), and take \( y \) to be one of such a column. Now we see

\[
\rho(x, \epsilon y) = |\epsilon| y^T My/(2|x^T y|) \to 0 \quad \text{as} \quad \epsilon \to 0.
\]

This gives (3.4) since \( \rho(\cdot, \cdot) \geq 0 \) always. To see “inf” cannot be replaced by “min”, we assume there were \( x \) and \( y \) such that \( x^T y \neq 0 \) and \( \rho(x, y) = 0 \). We note that \( \rho(x, y) = 0 \) and \( x^T y \neq 0 \) imply \( x^T Kx = y^T My = 0 \) which in turn implies \( Kx = My = 0 \), contradicting the assumption that the kernels and \( K \) and \( M \) are orthogonal to each other. \[\Diamond\]
Our next theorem – Theorem 3.2 – presents a subspace version of Theorem 3.1. It is the reason we mentioned in section 1 that the expression in (1.14) can be regarded as a proper subspace version of the Thouless functional in the form of \( \rho(\cdot, \cdot) \).

**Theorem 3.2.** Suppose that one of \( K \) and \( M \) is definite. Then we have

\[
\sum_{i=1}^{k} \lambda_i = \frac{1}{2} \inf_{U, V \in \mathbb{R}^{n \times k}} \trace(U^T K U + V^T M V). \tag{3.8}
\]

Moreover, “\( \inf \)” can be replaced by “\( \min \)” if and only if both \( K \) and \( M \) are definite. When they are definite and if also \( \lambda_k < \lambda_{k+1} \), then for any \( U \) and \( V \) that attain the minimum, \( \{ \text{span}(U), \text{span}(V) \} \) is a pair of deflating subspaces of \( \{ K, M \} \) and the corresponding \( H_\text{sr} \) (and \( H_R \), too) has eigenvalues \( \pm \lambda_i \) (1 \( \leq \) \( i \) \( \leq \) \( k \)).

**Proof.** The proof is long and deferred to appendix A. \( \Box \)

**Corollary 3.1.** Suppose that one of \( K \) and \( M \) is definite. Then

\[
\sum_{i=1}^{n} \lambda_i = \frac{1}{2} \inf_{U, V \in \mathbb{R}^{n \times n}} \trace(U^T K U + V^T M V). \tag{3.9}
\]

**Remark 3.2.** In (3.2) which is for the symmetric eigenvalue problem of \( A \), if \( k = n \), then

\[
\sum_{i=1}^{n} \theta_i = \trace(U^T A U), \tag{3.10}
\]

regardless of \( U \in \mathbb{R}^{n \times n} \) so long as \( U^T U = I_n \). There is certainly a strong resemblance between (3.9) and (3.10), but a fundamental difference, too. That is that “\( \inf \)” has to be there in (3.9). Without “\( \inf \)” (3.9) becomes

\[
\sum_{i=1}^{n} \lambda_i \leq \frac{1}{2} \trace(U^T K U + V^T M V) \tag{3.11}
\]

for any two \( U, V \in \mathbb{R}^{n \times n} \) satisfying \( U^T V = I_n \). \( \diamond \)

Exploiting the close relation through (1.7) between the two different forms of the Thouless functionals \( \rho(\cdot, \cdot) \) and \( \rho(\cdot, \cdot) \), we have by Theorem 3.2 the following theorem. It suggests that

\[
\frac{1}{2} \trace \left( \begin{bmatrix} U \\ V \end{bmatrix}^T \begin{bmatrix} A & B \\ B & A \end{bmatrix} \begin{bmatrix} U \\ V \end{bmatrix} \right)
\]

subject to

\[
U, V \in \mathbb{R}^{n \times k}, \quad U^T U - V^T V = 2I_k \quad \text{and} \quad U^T V = V^T U
\]

is a proper subspace version of the Thouless functional in the form of \( \rho(\cdot, \cdot) \).

**Theorem 3.3.** Suppose that \( A \) and \( B \) are \( n \times n \) real symmetric matrices and that \( A + B \) and \( A - B \) are positive semi-definite and one of them is definite, and \( U, V \in \mathbb{R}^{n \times k} \). Then

\[
\sum_{i=1}^{k} \lambda_i = \frac{1}{2} \inf_{U^T U - V^T V = 2I_k} \trace \left( \begin{bmatrix} U \\ V \end{bmatrix}^T \begin{bmatrix} A & B \\ B & A \end{bmatrix} \begin{bmatrix} U \\ V \end{bmatrix} \right). \tag{3.12}
\]

Moreover, “\( \inf \)” can be replaced by “\( \min \)” if and only if both \( A \pm B \) are definite.
Proof. Assume the assignments in (1.6) for \( K \) and \( M \). We have by (1.8)
\[
\begin{pmatrix} U \\ V \end{pmatrix}^T \begin{pmatrix} A & B \\ B & A \end{pmatrix} \begin{pmatrix} U \\ V \end{pmatrix} = \begin{pmatrix} V \\ U \end{pmatrix}^T \begin{pmatrix} M & K \\ K & U \end{pmatrix} = \hat{U}^T K \hat{U} + \hat{V}^T M \hat{V},
\]
where
\[
\begin{pmatrix} \hat{V} \\ \hat{U} \end{pmatrix} = J^T \begin{pmatrix} U \\ V \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} U + V \\ U - V \end{pmatrix}.
\]
Therefore
\[
\inf_{U^T V = I_k} \text{trace}(\hat{U}^T K \hat{U} + \hat{V}^T M \hat{V}) = \inf_{(U-V)^T (U+V) = 2I_k} \text{trace}(\begin{pmatrix} U \\ V \end{pmatrix}^T \begin{pmatrix} A & B \\ B & A \end{pmatrix} \begin{pmatrix} U \\ V \end{pmatrix}).
\]

We claim
\[
(U - V)^T (U + V) = 2I_k \iff U^T U - V^T V = 2I_k \text{ and } U^T V = V^T U.
\]
This is because \((U - V)^T (U + V) = 2I_k\) and its transpose version give
\[
\begin{align*}
U^T U + U^T V - V^T U - V^T V &= 2I_k, \\
U^T U + V^T U - U^T V - V^T V &= 2I_k.
\end{align*}
\]
Add both equations in (3.15) to get \(U^T U - V^T V = 2I_k\) and subtract one from the other to get \(U^T V = V^T U\). That the right-hand side in (3.14) implies its left-hand side can be seen from any of the equations in (3.15). Equation (3.12) is now a consequence of Theorem 3.2, (3.13), and (3.14).

3.2 Cauchy-like interlacing inequalities

In the following Theorem 3.4, we obtain inequalities that can be regarded as an extension of Cauchy interlacing inequalities (3.3).

**Theorem 3.4.** Suppose that one of \( K \) and \( M \) is definite. Let \( U, V \in \mathbb{R}^{n \times k} \) such that \( U^T V \) is nonsingular. Write \( W = U^T V = W_1^T W_2 \), where \( W_i \in \mathbb{R}^{k \times k} \) are nonsingular, and define \( H_{\text{sr}} \) by (2.19). Denote by \( \pm \mu_i (1 \leq i \leq k) \) the eigenvalues of \( H_{\text{sr}} \), where \( 0 \leq \mu_1 \leq \cdots \leq \mu_k \). Then
\[
\lambda_i \leq \mu_i \leq \sqrt{\min \{\kappa(K), \kappa(M)\}} \cos \angle(\mathcal{U}, \mathcal{V}) \lambda_{i+n-k} \quad \text{for } 1 \leq i \leq k,
\]
where \( \mathcal{U} = \text{span}(U) \) and \( \mathcal{V} = \text{span}(V) \). Furthermore, if \( \lambda_k < \lambda_{k+1} \) and \( \lambda_i = \mu_i \) for \( 1 \leq i \leq k \), then\(^3\)
\[
\begin{enumerate}
\item \( \mathcal{U} = \text{span}(X_{(1:k,:)}(1:k,:)) \) when \( M \) is definite, where \( X \) is as in Theorem 2.3;
\item \( \{\mathcal{U}, \mathcal{V}\} \) is a pair of deflating subspaces of \( \{K, M\} \) corresponding to the eigenvalues \( \pm \lambda_i (1 \leq i \leq k) \) of \( H \) when both \( K \) and \( M \) are definite.
\end{enumerate}
\]

**Proof.** The proof is long and deferred to appendix A.
\(\square\)

\(^3\)A similar statement for the case in which \( K \) is definite (but \( M \) is semi-definite) can be made, noting that the decompositions in (2.5) no longer hold but similar decompositions exist.
Corollary 3.2. Suppose that one of $K, M \in \mathbb{R}^{n \times n}$ is definite. Let $K_p$ and $M_p$ be $k \times k$ principal submatrices of $K$ and $M$, extracted with same row and column indices for both. Denote by $\pm \mu_i$ ($1 \leq i \leq k$) the eigenvalues of $\begin{pmatrix} 0 & K_p \\ M_p & 0 \end{pmatrix}$, where $0 \leq \mu_1 \leq \cdots \leq \mu_k$. Then

$$\lambda_i \leq \mu_i \leq \sqrt{\min \{\kappa(K), \kappa(M)\}} \lambda_{i+n-k} \quad \text{for } 1 \leq i \leq k.$$  

(3.17)

Proof. Let $i_1, i_2, \ldots, i_k$ be the row and column indices of $K$ and $M$ that give $K_p$ and $M_p$, and let $U = (e_{i_1}, e_{i_2}, \ldots, e_{i_k}) \in \mathbb{R}^{n \times k}$. Then $K_p = U^T K U$ and $M_p = U^T M U$. Apply Theorem 3.4 with $V = U$ to conclude the proof.

Inequalities (3.16) and (3.17) mirror Cauchy interlacing inequalities (3.3). But the upper bounds on $\mu_i$ by (3.16) and (3.17) are more complicated. The following example shows that the factor $[\cos \angle(U,V)]^{-1}$ in general cannot be removed. Consider

$$K = \begin{pmatrix} \alpha^2 & 0 \\ 0 & \beta^2 \end{pmatrix}, \quad M = I_2, \quad U = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad V = \begin{pmatrix} t \\ 1 \end{pmatrix},$$

where $0 < \alpha < \beta$ and $t = \tan \angle(U,V)$. Then the positive eigenvalue of $H_{su}$ is

$$\sqrt{U^T K U V^T M V} = \beta \sqrt{1 + t^2} = \frac{\beta}{\cos \angle(U,V)}.$$  

We suspect that $\sqrt{\min \{\kappa(K), \kappa(M)\}}$ could be removed or at least be replaceable by something that does not depend on the condition numbers, but we have no proof, except a special case as detailed in the following theorem.

Theorem 3.5. Under the assumptions of Theorem 3.4, if either $U \subseteq MV$ when $M$ is definite or $V \subseteq KU$ when $K$ is definite, then

$$\lambda_i \leq \mu_i \leq \lambda_{i+n-k} \quad \text{for } 1 \leq i \leq k.$$  

(3.18)

Proof. We will prove (3.18), assuming $M$ is definite and $U \subseteq MV$. Since $M$ is definite, $\dim(MV)^\perp = n - k$, where $(MV)^\perp$ is the orthogonal complement of $MV$. Let $V_\perp \in \mathbb{R}^{n \times (n-k)}$ be a basis matrix of $(MV)^\perp$. Then $V_\perp^T M V = 0$ and also $U^T V_\perp = 0$ because $U \subseteq MV$. Let

$$U = \left(U W_{1}^{-1}, MV_\perp (V_\perp^T M V_\perp)^{-1/2}\right), \quad V = \left(V W_{2}^{-1}, V_\perp (V_\perp^T M V_\perp)^{-1/2}\right).$$

It can be verified that $U^T V = I_n$ (which implies $V^T U = I_n$ also) and

$$\widetilde{M} \overset{\text{def}}{=} V^T M V = \begin{pmatrix} W_2^{-1} V^T M V W_2^{-1} & 0 \\ 0 & I_{n-k} \end{pmatrix}.$$  

Let $\hat{K} = U^T K U$. Notice that

$$\text{eig}(\hat{K} \widetilde{M}) = \text{eig}(\widetilde{M}^{1/2}) \hat{K} \widetilde{M}^{1/2}) = \{\lambda_i^2, i = 1, 2, \ldots, n\},$$

where eig(·) is the set of eigenvalues of a matrix. The $k \times k$ leading principal matrix of $\widetilde{M}^{1/2} \hat{K} \widetilde{M}^{1/2}$ is

$$(W_2^{-1} V^T M V W_2^{-1})^{1/2}(W_1^{-1} U^T K U W_1^{-1})(W_2^{-1} V^T M V W_2^{-1})^{1/2}$$

whose eigenvalues are $\mu_i^2$, $i = 1, 2, \ldots, k$. Apply Cauchy interlacing inequalities [16] to get

$$\lambda_i^2 \leq \mu_i^2 \leq \lambda_{i+n-k}^2 \quad \text{for } 1 \leq i \leq k$$

which yield (3.18).
3.3 Minimization principle and deflation

Deflation is a commonly used technique in solving eigenvalue problems. The basic idea is to avoid computing these eigenpairs that have been already computed to a prescribed accuracy, and it is accomplished by orthogonalizing current vectors against all already converged eigenvectors. Return to the symmetric eigenvalue problem for $A$ we discussed at the beginning of this section. Denote by $x_i$ ($1 \leq i \leq n$) the eigenvectors of $A$ corresponding to $\theta_i$. We may assume $x_i^T x_j = 0$ for $i \neq j$. In (3.1), if “min” is restricted to all $x$ that is orthogonal to $x_i$ ($1 \leq i \leq \ell$), then the minimum becomes $\theta_{\ell+1}$. Similarly, if $U$ is restricted to those such that $U^T x_i = 0$ ($1 \leq i \leq \ell$), then the minimum in (3.2) is $\sum_{i=1}^k \theta_{\ell+i}$, and (3.3) becomes $\theta_{\ell+i} \leq \mu_i \leq \theta_{\ell+n-k}$. The next theorem gives similar results for $H$.

**Theorem 3.6.** Suppose that $K$ and $M$ are symmetric positive definite. Denote by $z_i = \begin{pmatrix} y_i \\ x_i \end{pmatrix}$ ($1 \leq i \leq n$) the eigenvectors of $H$ corresponding to the positive eigenvalues $\lambda_i$, respectively, where all $x_i$, $y_i \in \mathbb{R}^n$. Suppose that $\langle z_i, z_j \rangle_\mathcal{S} = z_i^T \mathcal{S} z_j = 0$ for $i \neq j$. Set $Y_1 = (y_1, y_2, \ldots, y_\ell)$ and $X_1 = (x_1, x_2, \ldots, x_\ell)$.

1. We have
   \[ \sum_{i=1}^k \lambda_{\ell+i} = \frac{1}{2} \inf_{U, V \in \mathbb{R}^{n \times k}, V^T V = I_k \text{ trace}(U^T K U + V^T M V).} \] (3.19)

   If also $\lambda_{\ell+k} < \lambda_{\ell+k+1}$, then for any $U$ and $V$ that attain the minimum, $\{\text{span}(U), \text{span}(V)\}$ is a pair of deflating subspaces of $\{K, M\}$ corresponding to the eigenvalues $\pm \lambda_{\ell+i}$ ($1 \leq i \leq k$) of $H$.

2. Let $U, V \in \mathbb{R}^{n \times k}$ such that $U^T V$ is nonsingular, $U^T Y_1 = 0$ and $V^T X_1 = 0$. Write $W = U^T V = W_1^T W_2$, where $W_1 \in \mathbb{R}^{k \times k}$ are nonsingular, and define $H_{\text{Sn}}$ by (2.19). Denote by $\pm \mu_i$ ($1 \leq i \leq k$) the eigenvalues of $H_{\text{Sn}}$, where $0 \leq \mu_1 \leq \cdots \leq \mu_k$. Then
   \[ \lambda_{\ell+i} \leq \mu_i \leq \sqrt{\min(\kappa(K), \kappa(M))} \frac{\lambda_{\ell+n-k}}{\cos \angle(U, V)} \] (3.20)

   If $\lambda_{\ell+k} < \lambda_{\ell+k+1}$ and if $\lambda_{\ell+i} = \mu_i$ for $1 \leq i \leq k$, then $\{\text{span}(U), \text{span}(V)\}$ is a pair of deflating subspaces of $\{K, M\}$ corresponding to the eigenvalues $\pm \lambda_{\ell+i}$ ($1 \leq i \leq k$) of $H$.

**Proof.** See appendix A. \qed

4 Conclusion remarks

We have uncovered new minimization principles and Cauchy-like interlacing inequalities for the LR (a.k.a. RPA) eigenvalue problem arising from the calculation of excitation states of many-particle systems in computational quantum chemistry and physics. In addition, we also obtained a structure-preserving projection $H_{\text{SR}}$ of $H$ onto a pair of subspaces. The role of $H_{\text{SR}}$ for the LR eigenvalue problem (1.1) in many ways is the same as the Rayleigh quotient matrix for the symmetric eigenvalue problem. These new results mirror the three well-known results for the LR eigenvalue problem (1.1) in many ways is the same as the Rayleigh quotient matrix for the symmetric eigenvalue problem. These new results mirror the three well-known results for the symmetric eigenvalue problem. They lay the foundation for our numerical investigation in the second paper of this sequel where new efficient numerical methods will

---

4 By Theorem 2.2, $\langle z_i, z_j \rangle_\mathcal{S} = z_i^T \mathcal{S} z_j = 0$ if $\lambda_i \neq \lambda_j$. In the case when $\lambda_i$ is a multiple eigenvalue, $H$ has an invariant subspace whose dimension is the same as the algebraic multiplicity of $\lambda_i$ because $H$ is diagonalizable by Theorem 2.3. Item 1. of Theorem 2.2 guarantees that the invariant subspace has an $\langle \cdot, \cdot \rangle_\mathcal{S}$-orthogonal basis.
be devised for computing the first few smallest positive eigenvalues and their corresponding eigenvectors simultaneously.

Although, throughout this paper and its following one, it is assumed both $K$ and $M$ are real matrices, all results are valid for Hermitian positive semi-definite $K$ and $M$ with one of them being definite after minor changes: replacing all $\mathbb{R}$ by $\mathbb{C}$ and all superscripts $(\cdot)^T$ by complex conjugate transposes $(\cdot)^H$.

The right inequalities in Theorem 3.4 and Corollary 3.2 that mirror Cauchy interlacing inequalities for the standard symmetric eigenvalue problem are not as satisfactory as we would like. We demonstrated that the factor $[\cos \angle(U, V)]^{-1}$ is in general not removable, but the factor $\sqrt{\min\{\kappa(K), \kappa(M)\}}$ could be an artifact of our proof and thus might be removed. No proof has been found yet.

**Acknowledgments**

We thank Dario Rocca and Giulia Galli for drawing our attentions to the linear response eigenvalue problem.

**A Proofs of Theorems 3.2 – 3.6**

**Lemma A.1.** Let $\omega_i \in \mathbb{R}$ for $1 \leq i \leq n$ be arranged in ascending order, i.e., $\omega_1 \leq \omega_2 \leq \cdots \leq \omega_n$, and let $\alpha_i \in \mathbb{R}$ for $1 \leq i \leq n$. Denote by $\alpha_i^\downarrow$ ($i = 1, \ldots, n$) the rearrangement of $\alpha_i$ ($i = 1, \ldots, n$) in descending order, i.e., $\alpha_1^\downarrow \geq \cdots \geq \alpha_n^\downarrow$. Then

$$\sum_{i=1}^{n} \omega_i \alpha_i \geq \sum_{i=1}^{n} \omega_i \alpha_i^\downarrow. \quad (A.1)$$

If (A.1) is an equality and if $\alpha_k > \alpha_{k+1}$ and $\omega_k < \omega_{k+1}$ for some $1 \leq k < n$, then

$$\{\alpha_j^\downarrow, j = 1, \ldots, k\} = \{\alpha_j, j = 1, \ldots, k\}. \quad (A.2)$$

**Proof.** Inequality (A.1) is well-known. See, for example, [4, (II.37) on p.49]. We now prove (A.2), under the conditions that (A.1) is an equality, $\alpha_1^\downarrow > \alpha_2^\downarrow$, and $\omega_k < \omega_{k+1}$. Suppose, to the contrary, that (A.2) did not hold. Then there would exist

$$\ell_1 \leq k \text{ and } \ell_2 > k \text{ such that } \alpha_{\ell_1} = \alpha_{\ell_2}^\downarrow;$$

$$j_1 \leq k \text{ and } j_2 > k \text{ such that } \alpha_{j_1}^\downarrow = \alpha_{j_2}.$$ 

Since

$$\omega_i \alpha_{\ell_1} + \omega_j \alpha_{j_2} - (\omega_i \alpha_{j_2} + \omega_j \alpha_{\ell_1}) = (\alpha_{j_2} - \alpha_{\ell_1})(\omega_j - \omega_{\ell_1})$$

$$= (\alpha_{j_2}^\downarrow - \alpha_{\ell_1}^\downarrow)(\omega_j - \omega_{\ell_1})$$

$$\geq (\alpha_k^\downarrow - \alpha_{k+1}^\downarrow)(\omega_{k+1} - \omega_k)$$

$$> 0,$$

we have

$$\sum_{i=1}^{n} \omega_i \alpha_i = \sum_{i \neq \ell_1, j_2} \omega_i \alpha_i + \omega_\ell_1 \alpha_\ell_1 + \omega_{j_2} \alpha_{j_2} > \sum_{i \neq \ell_1, j_2} \omega_i \alpha_i + \omega_\ell_1 \alpha_\ell_1 + \omega_{j_2} \alpha_{j_2} + \omega_j \alpha_{\ell_1} \geq \sum_{i=1}^{n} \omega_i \alpha_i^\downarrow,$$

contradicting that (A.1) is an equality. This proves (A.2).
Lemma A.2. Let \( U \in \mathbb{R}^{n \times k} \) and \( \Omega = \text{diag}(\omega_1, \omega_2, \ldots, \omega_n) \), where \( \omega_1 \leq \omega_2 \leq \cdots \leq \omega_n \). Then
\[
\text{trace}(U^T \Omega U) \geq \sum_{i=1}^{k} \sigma_i^2 \omega_i,
\]
where \( \sigma_i (i = 1, \ldots, k) \) are the \( k \) singular values of \( U \) in descending order, i.e., \( \sigma_1 \geq \cdots \geq \sigma_k \geq 0 \).

If (A.3) is an equality, \( \omega_k < \omega_{k+1} \), and \( \sigma_k > 0 \), then \( U_{(k+1:n,:)} = 0 \), i.e., the last \( n-k \) rows of \( U \) are zeros.

Proof. Write \( \alpha_i = (UU^T)_{(i,i)} \), the \( i \)th diagonal entry of \( UU^T \). By Lemma A.1,
\[
\text{trace}(U^T \Omega U) = \text{trace}(UU^T \Omega) = \sum_{i=1}^{n} \omega_i \alpha_i \geq \sum_{i=1}^{n} \omega_i \alpha_i^T,
\]
where \( \alpha_i^T (i = 1, \ldots, n) \) are defined as in Lemma A.1. Since \( UU^T \) is symmetric positive semi-definite, its diagonal entries: \( \alpha_i (i = 1, \ldots, n) \) are majorized by its \( n \) eigenvalues: \( \sigma_i^2 (i = 1, \ldots, k) \) and \( \sigma_i^2 = 0 \) (\( i = k+1, \ldots, n \)) \cite[(II.14) on p.35]{10}, meaning
\[
\sum_{i=1}^{n} \omega_i \alpha_i^T \geq \sum_{i=1}^{k} \omega_i \sigma_i^2.
\]

Therefore, by \cite[Lemma 2.3]{10},
\[
\sum_{i=1}^{n} \omega_i \alpha_i^T \geq \sum_{i=1}^{k} \omega_i \sigma_i^2
\]
which, combined with (A.4), lead to (A.3). But in order to characterize those matrices \( U \) that make (A.3) an equality, we need to look into when (A.6) becomes an equality. To that end, we still have to give a proof of (A.6), despite of \cite[Lemma 2.3]{10}. Let \( t_0 = s_0 = 0 \). We have
\[
\sum_{i=1}^{n} \omega_i \alpha_i^T = \sum_{i=1}^{n} \omega_i (t_i - t_{i-1})
= \omega_n t_n + \sum_{i=1}^{n-1} (\omega_i - \omega_{i+1}) t_i
\geq \omega_n s_n + \sum_{i=1}^{n-1} (\omega_i - \omega_{i+1}) s_i
= \sum_{i=1}^{n} \omega_i \sigma_i^2 = \sum_{i=1}^{k} \omega_i \sigma_i^2, \quad (\sigma_i = 0 \text{ for } i > k)
\]
This is (A.6).

Now if (A.3) is an equality and if \( \omega_k < \omega_{k+1} \), then the equal sign in (A.7) must hold and thus \( t_k = s_k \) because \( \omega_k - \omega_{k+1} < 0 \). It follows from \( \sigma_i^2 = 0 \) (\( i = k+1, \ldots, n \)) that \( t_k = s_k = \cdots = s_n = t_n \); so \( \alpha_i^T = 0 \) for \( j > k \) by (A.5). Because (A.4) must be an equality, \( \alpha_k^T > 0 = \alpha_{k+1}^T \) (since \( \sigma_k > 0 \)), and \( \omega_k < \omega_{k+1} \), we conclude by Lemma A.1 that (A.2) holds, and thus \( \alpha_j = (UU^T)_{(j,j)} = 0 \) for \( j > k \) which implies
\[
(UU^T)_{(i,j)} = 0 \quad \text{for } \max \{i, j\} > k
\]
because \( UU^T \) is symmetric positive semi-definite. In particular
\[
U_{(k+1:n,:)} U_{(k+1:n,:)}^T = (UU^T)_{(k+1:n,k+1:n)} = 0
\]
which implies \( U_{(k+1:n,:)} = 0 \), as expected. \qed
\textbf{Proof of Theorem 3.2.} Suppose that $M$ is definite. Equations in (2.5) hold for some non-singular $Y \in \mathbb{R}^{n \times n}$ and $X = Y^{-T}$. We have by (2.5)

\[ U^T K U + V^T M V = U^T Y A^2 Y^T U + V^T X X^T V = \hat{U}^T A^2 \hat{U} + \hat{V}^T \hat{V}, \]  

(A.8)

where $\hat{U} = Y^T U$ and $\hat{V} = X^T V$. It can be verified that $\hat{U}^T \hat{V} = U^T V$ and that the correspondences between $U$ and $\hat{U}$ and between $V$ and $\hat{V}$ are one-one. Therefore

\[ \inf_{U^T V = I_k} \text{trace}(U^T K U + V^T M V) = \inf_{U^T V = I_k} \text{trace}(\hat{U}^T A^2 \hat{U} + \hat{V}^T \hat{V}). \]  

(A.9)

For any given $\hat{U}$ and $\hat{V}$, denote their singular values, respectively, by $\alpha_i$ $(i = 1, \ldots, k)$ and $\beta_i$ $(i = 1, \ldots, k)$ in descending order. Then by Lemma A.2

\[ \text{trace}(\hat{U}^T A^2 \hat{U} + \hat{V}^T \hat{V}) \geq \sum_{i=1}^{k} \alpha_i^2 \lambda_i^2 + \sum_{i=1}^{k} \beta_i^2 \]  

(A.10)

\[ = \sum_{i=1}^{k} (\alpha_i^2 \lambda_i^2 + \beta_i^2) \]  

\[ \geq 2 \sum_{i=1}^{k} \alpha_i \beta_{i-1} \lambda_i \]  

(A.11)

\[ \geq 2 \sum_{i=1}^{k} \lambda_i. \]  

(A.12)

The last inequality holds because of [8, (3.3.18) on p.178] which says $\alpha_i \beta_{i-1}$ is greater or equal to the $k$th largest singular value of $U^T V = I_k$ which is 1. Combine (A.9) and (A.12) to get

\[ \frac{1}{2} \inf_{U^T V = I_k} \text{trace}(U^T K U + V^T M V) \geq \sum_{i=1}^{k} \lambda_i. \]  

(A.13)

Now if all $\lambda_i > 0$ (i.e., $K$ is also definite), then it can be seen that picking $U$ and $V$ such that

\[ \hat{U} = \begin{pmatrix} \text{diag}(\lambda_1^{-1/2}, \ldots, \lambda_k^{-1/2}) \\ 0 \end{pmatrix}, \quad \hat{V} = \begin{pmatrix} \text{diag}(\lambda_1^{1/2}, \ldots, \lambda_k^{1/2}) \\ 0 \end{pmatrix}, \]

gives $\frac{1}{2} \text{trace}(U^T K U + V^T M V) = \sum_{i=1}^{k} \lambda_i$ which, together with (A.13), yield (3.8) with “inf” replaced by “min”.

When $K$ is singular, $\lambda_1 = 0$ and (A.11) is always a strict inequality. So

\[ \frac{1}{2} \text{trace}(U^T K U + V^T M V) > \sum_{i=1}^{k} \lambda_i \quad \text{for any } U^T V = I_k. \]  

(A.14)

Suppose $0 = \lambda_1 = \cdots = \lambda_\ell < \lambda_{\ell+1} \leq \cdots \leq \lambda_k$. We pick $U$ and $V$ such that

\[ \hat{U} = \begin{pmatrix} \epsilon^{-1} I_\ell \bigg| \text{diag}(\lambda_{\ell+1}^{-1/2}, \ldots, \lambda_k^{-1/2}) \\ 0 \end{pmatrix}, \quad \hat{V} = \begin{pmatrix} \epsilon I_\ell \bigg| \text{diag}(\lambda_{\ell+1}^{1/2}, \ldots, \lambda_k^{1/2}) \\ 0 \end{pmatrix}. \]
Then \( \frac{1}{2} \text{trace}(U^T K U + V^T M V) = \sum_{i=1}^{k} \lambda_i + \epsilon^2 \) which goes to \( \sum_{i=1}^{k} \lambda_i \) as \( \epsilon \to 0 \). So we have (3.8) by (A.14), and “inf” cannot be replaced by “min”.

Now suppose \( 0 < \lambda_1 \) and \( \lambda_k < \lambda_{k+1} \) and suppose that \( U \) and \( V \) attain the minimum, i.e.,

\[
\frac{1}{2} \text{trace}(U^T K U + V^T M V) = \sum_{i=1}^{k} \lambda_i.
\]

For this to happen, all equal signs in (A.10), (A.11), and (A.12) must take place. For the equality sign in (A.10) to take place, by Lemma A.2 we have \( \hat{U}_{(k+1:n, :)} = 0 \). Partition

\[
\hat{U} = \begin{pmatrix} 
\hat{U}_1 \\
0 
\end{pmatrix}, \quad \hat{V} = \begin{pmatrix} 
\hat{V}_1 \\
\hat{V}_2 
\end{pmatrix}, \quad \hat{U}_1, \hat{V}_1 \in \mathbb{R}^{k \times k}.
\]

We claim \( \hat{V}_2 = 0 \), too. Here is why. For the equality sign in (A.12) to take place, we have \( \alpha_i \beta_{k-i+1} = 1 \) for \( 1 \leq i \leq k \). Now \( I_k = \hat{U}^T \hat{V} = \hat{U}_1^T \hat{V}_1 \) implies \( \alpha_i \gamma_{k-i+1} \geq 1 \) [8, (3.3.18) on p.178], where \( \gamma_i \) (\( i = 1, \ldots, k \)) are the singular values of \( \hat{V}_1 \) in descending order. Since \( \hat{V}^T \hat{V} = \hat{V}_1^T \hat{V}_1 + \hat{V}_2^T \hat{V}_2 \), we have \( \gamma_i \leq \beta_i \) for \( 1 \leq i \leq k \) and thus

\[
1 \leq \alpha_i \gamma_{k-i+1} \leq \alpha_i \beta_{k-i+1} = 1
\]

which implies \( \gamma_i = \beta_i \) for \( 1 \leq i \leq k \). So \( \hat{V}_2 = 0 \). Now use \( U = X \hat{U} \) and \( V = Y \hat{V} \) to conclude that \( \{\text{span}(U), \text{span}(V)\} \) is the pair of deflating subspaces of \( \{K, M\} \) corresponding to the eigenvalues \( \pm \lambda_i \) (\( 1 \leq i \leq k \)) of \( H \).

\[\square\]

**Proof of Theorem 3.4.** Assume that \( M \) is definite. Without loss of generality, we may simply assume \( U^T V = I_k \) and \( W_1 = W_2 = I_k \); otherwise substitutions:

\[
U \leftarrow U W_1^{-1}, \quad V \leftarrow V W_2^{-1}, \quad I_k \leftarrow W_1, \quad I_k \leftarrow W_2,
\]

will give new \( U \) and \( V \) with \( U^T V = I_k \) and at the same time the same \( H_{sr} \).

Equations in (2.5) hold for some nonsingular \( Y \in \mathbb{R}^{n \times n} \) and \( X = Y^{-T} \). Then

\[
U^T K U = U^T Y A Y^T U = \hat{U}^T A^2 \hat{U}, \quad \tag{A.15a}
\]
\[
V^T M V = V^T X X^T V = \hat{V}^T \hat{V}, \quad \tag{A.15b}
\]

where \( \hat{U} = Y^T U \) and \( \hat{V} = X^T V \). Still \( \hat{U}^T \hat{V} = U^T V = I_k \). Decompose \( \hat{V} \) as

\[
\hat{V} \overset{\text{def}}{=} Q^T \hat{V} = \begin{pmatrix} 
\hat{V}_1 \\
0 
\end{pmatrix}, \quad Q^T Q = I_n, \quad \hat{V}_1 \text{ nonsingular.} \quad \tag{A.16}
\]

This can be proved, for example, using SVD of \( \hat{V} \). Then \( \hat{V}^T \hat{V} = \hat{V}_1^T \hat{V}_1 \). Partition

\[
\hat{U} \overset{\text{def}}{=} Q^T \hat{U} = \begin{pmatrix} 
\hat{U}_1 \\
\hat{U}_2 
\end{pmatrix}, \quad \hat{U}_1 \in \mathbb{R}^{k \times k}. \quad \tag{A.17}
\]

Then \( \hat{U}^T \hat{V} = (Q^T \hat{U})^T Q^T \hat{V} = \hat{U}_1^T \hat{V}_1 = I_k \) which implies \( \hat{U}_1^T = \hat{V}_1^{-1} \). Set

\[
A = Q^T A^2 Q, \quad E = \hat{U}_2 \hat{V}_1^T \quad \tag{A.18}
\]

so as to get

\[
\hat{U}^T A^2 \hat{U} = \hat{U}^T A \hat{U}, \quad \hat{U} \hat{V}_1^T = \begin{pmatrix} I_k \\
0 
\end{pmatrix}. \quad \tag{A.19}
\]
By Theorem 2.1, \( \mu_i^2 (1 \leq i \leq k) \) are all the eigenvalues of
\[
(UTKU) (VTM) = (\hat{U}^T A^2 \hat{U}) (V^T \hat{V}) = (\hat{U}^T A \hat{U}) (\hat{V}_1^T \hat{V}_1)
\]
whose eigenvalues are the same as \( \hat{V}_1 (\hat{U}^T A \hat{U}) \hat{V}_1^T \), a real symmetric positive semi-definite matrix.
Set
\[
P = \hat{U} \hat{V}_1^T (I_k + E^T E)^{-1/2}.
\]
Then \( P^T P = I_k \) by (A.19). Denote by \( \nu_i \) the eigenvalues of \( P^T A P \) in ascending order. We have
\[
\lambda_i^2 \leq \nu_i \leq \lambda_{i+n-k}^2 \quad \text{for} \ 1 \leq i \leq k
\]
by Cauchy interlacing theorem [16, 21]. For any \( \hat{u} \in \mathbb{R}^k \), letting \( u = (I_k + E^T E)^{1/2} \hat{u} \) gives
\[
(1 + \|E\|^2_{2}) \frac{u^T (P^T A P) u}{u^T u} \geq \frac{\hat{u}^T \left[ \hat{V}_1 (\hat{U}^T A \hat{U}) \hat{V}_1^T \right] \hat{u}}{\hat{u}^T \hat{u}} \geq \frac{u^T (P^T A P) u}{u^T u}
\]
which means, in proving this theorem, we can use \( u \) from different basis matrices for \( U \) and \( V \).

Denote by \( U_1 \) and \( U_2 \) subspaces of \( \mathbb{R}^k \) of dimension \( i \). Using the Courant-Fisher min-max principle (see [16, p.206], [21, p.201]), we have
\[
\mu_i^2 = \min_{U_i} \max_{\hat{u} \in U_i} \frac{\hat{u}^T \left[ \hat{V}_1 (\hat{U}^T A \hat{U}) \hat{V}_1^T \right] \hat{u}}{\hat{u}^T \hat{u}}
\]
\[
\geq \min_{U_i = (I_k + E^T E)^{1/2} U_i} \max_{\hat{u} \in U_i} \frac{u^T (P^T A P) u}{u^T u} \quad \text{(by (A.22))}
\]
\[
= \min_{U_i} \max_{u \in U_i} \frac{u^T (P^T A P) u}{u^T u}
\]
\[
= \nu_i \geq \lambda_i^2,
\]
\[
\mu_i^2 \geq (1 + \|E\|^2_{2}) \nu_i \leq (1 + \|E\|^2_{2}) \lambda_{i+n-k}^2.
\]

It remains to bound \( 1 + \|E\|^2_{2} \). We have from (A.16) – (A.19)
\[
\sqrt{1 + \|E\|^2_{2}} = \|\hat{U} \hat{V}_1^T\|_2 \leq \|\hat{U}\|_2 \|\hat{V}_1\|_2
\]
\[
= \|\hat{U}\|_2 \|\hat{V}\|_2 = \|Y^T U\|_2 \|X^T V\|_2
\]
\[
\leq \|Y\|_2 \|Y^{-1}\|_2 \|U\|_2 \|V\|_2 = \sqrt{\kappa(M)} \|U\|_2 \|V\|_2.
\]

In Theorem 2.7, we proved that the eigenvalues of \( H_{sr} \) do not changes with respect to the choices of basis matrices. Which means, in proving this theorem, we can use \( H_{sr} \) constructed from different basis matrices for \( U \) and \( V \). What we are going to do is to pick new \( U \) and \( V \) such that the right hand side of (A.23) is
\[
\frac{\sqrt{\kappa(M)}}{\cos \angle(U, V)}.
\]
To this end, we compute QR decompositions
\[
U = Q_1 R_1, \quad V = Q_2 R_2,
\]
and
\[
\cos \angle(U, V) = \frac{\sqrt{\kappa(M)}}{\|U\|_2 \|V\|_2}.
\]
where $Q_1, Q_2 \in \mathbb{R}^{n \times k}$ have orthonormal columns. By [21, Theorem 5.2 on p.40], there are orthogonal matrices $P \in \mathbb{R}^{n \times n}$ and $S_1, S_2 \in \mathbb{R}^{k \times k}$ such that

\[ PQ_1 S_1 = \begin{pmatrix} k & \Gamma \\ n-2k & 0 \end{pmatrix}, \quad PQ_2 S_2 = \begin{pmatrix} k & \Sigma \\ n-2k & 0 \end{pmatrix} \quad \text{if } 2k \leq n, \tag{A.24a} \]

\[ PQ_1 S_1 = \begin{pmatrix} n-k & 2k-n \\ 0 & I \end{pmatrix}, \quad PQ_2 S_2 = \begin{pmatrix} n-k & 0 \\ 0 & I \end{pmatrix} \quad \text{if } 2k > n, \tag{A.24b} \]

where $\Gamma = \text{diag}(\gamma_1, \ldots, \gamma_\ell)$ and $\Sigma = \text{diag}(\sigma_1, \ldots, \sigma_\ell)$, $\ell = k$ or $n-k$, all $\gamma_i, \sigma_i \geq 0$ and $\gamma_i^2 + \sigma_i^2 = 1$. With (A.24), we pick new $U$ and $V$ to be

\[
P^T \begin{pmatrix} \Gamma^{-1} \\ 0 \end{pmatrix}, \quad P^T \begin{pmatrix} \Sigma \\ 0 \end{pmatrix} \quad \text{if } 2k \leq n, 
\]

\[
P^T \begin{pmatrix} \Gamma^{-1} & 0 \\ 0 & I_{2n-k} \end{pmatrix}, \quad P^T \begin{pmatrix} \Gamma & 0 \\ 0 & I_{2n-k} \end{pmatrix} \quad \text{if } 2k > n,
\]

respectively. These new $U$ and $V$ span the same space as the old $U$ and $V$ and satisfy $U^T V = I_k$ and $\|U\|_2 \|V\|_2 = [\cos \angle(U, V)]^{-1}$. The proof of (3.16) is completed for the case when $M$ is definite.

Now if $\lambda_k < \lambda_{k+1}$ and $\mu_i = \mu_i$ for all $i = 1, 2, \ldots, k$, then $\nu_i = \lambda_i^2$ for all $i = 1, 2, \ldots, k$ since $\mu_i^2 \geq \nu_i \geq \lambda_i^2$. In particular, $\text{trace}(P^T A P) = \sum_{i=1}^k \lambda_i^2$. Apply [10, Theorem 2.2] or [9, Theorem 4] on $-A = Q^T (-A^2) Q$ to conclude that $(QP)_{(1:k, :)}$ is orthogonal and $(QP)_{(k+1:n, :)} = 0$. Write

\[
\hat{U} = \begin{pmatrix} \hat{U}_1 \\ \hat{U}_2 \end{pmatrix}, \quad \hat{V} = \begin{pmatrix} \hat{V}_1 \\ \hat{V}_2 \end{pmatrix}, \quad \hat{U}_1, \hat{V}_1 \in \mathbb{R}^{k \times k}, \quad A_i^2 = \text{diag}(\lambda_1^2, \ldots, \lambda_k^2).
\]

Since $Q P = \hat{U} \hat{V}^T (I_k + E^T E)^{-1/2}$ by (A.17), we conclude that $\hat{U}_2 = 0$ and thus $U = \text{span}(X_{(1:k, :)})$. Use $\hat{U}^T \hat{V} = I_k$ to get $\hat{U}_1^T \hat{V}_1 = I_k$ or equivalently $\hat{U}_1^T = \hat{V}_1^{-1}$. Note, by (A.20),

\[
(U^T K U)(V^T M V) = \hat{U}_1^T A_i^2 \hat{U}_1 \hat{V}_1^T \hat{V}
\]

which has the same eigenvalues as $A_i^2 \hat{U}_1 \hat{V}_1^T \hat{V} \hat{U}_1^T$, which has the same eigenvalues as

\[
A_1 \hat{U}_1 \hat{V}_1^T \hat{V} \hat{U}_1^T A_1 = A_1^2 + A_1 \hat{U}_1 \hat{V}_2^T \hat{V} \hat{U}_1^T A_1.
\]

Since by assumption the eigenvalues of $(U^T K U)(V^T M V)$ are $\lambda_i^2$ ($1 \leq i \leq k$), we have

\[
\sum_{i=1}^k \lambda_i^2 = \text{trace}(A_i^2 + A_1 \hat{U}_1 \hat{V}_2^T \hat{V} \hat{U}_1^T A_1) = \sum_{i=1}^k \lambda_i^2 + \text{trace}(A_1 \hat{U}_1 \hat{V}_2^T \hat{V} \hat{U}_1^T A_1)
\]

which implies $\text{trace}(A_1 \hat{U}_1 \hat{V}_2^T \hat{V} \hat{U}_1^T A_1) = 0$ and thus if $\lambda_1 > 0$, then $\hat{V}_2 \hat{U}_1^T = 0 \Rightarrow \hat{V}_2 = 0$. Therefore

\[
U = X \hat{U} = X_{(1:k, :)} \hat{U}_1, \quad V = Y \hat{V} = Y_{(1:k, :)} \hat{V}_1,
\]

as expected. \hfill \Box
Proof of Theorem 3.6. Equations in (2.5) hold for some nonsingular \( Y \in \mathbb{R}^{n \times n} \) and \( X = Y^{-T} \). Since the columns of \( Z = \begin{pmatrix} YA \\ X \end{pmatrix} \) are the eigenvectors of \( H \) corresponding to \( \lambda_i \) (\( i = 1, 2, \ldots, n \)) and the eigenvectors corresponding to a multiple \( \lambda_i \) can be picked as any \( \langle \cdot, \cdot \rangle \)-orthogonal basis vectors of the associated invariant subspace, we may assume that \( z_i \) is parallel to \( Z_{(:,i)} \), the \( i \)th column of \( Z \). Now for any \( U^T X_1 = 0 \) and \( V^T Y_1 = 0 \), \( \hat{U}^T \Lambda_2 \hat{U} \) and \( \hat{V}^T \hat{V} \) in (A.8) and (A.15) become
\[
\hat{U}^T \Lambda_2 \hat{U} = \hat{U}_2^T \Lambda_2^2 \hat{U}_2, \quad \hat{V}^T \hat{V} = \hat{V}_2^T \hat{V}_2,
\]
where
\[
\hat{U} = \ell_{n-\ell} \begin{pmatrix} 0 \\ \hat{U}_2 \end{pmatrix}, \quad \hat{V} = \ell_{n-\ell} \begin{pmatrix} 0 \\ \hat{V}_2 \end{pmatrix}, \quad A_2 = \text{diag}(\lambda_{\ell+1}, \ldots, \lambda_n).
\]
The rest of the proof are the same as the corresponding parts in the proofs of Theorems 3.2 and 3.4. \( \square \)
