Introduction

What Is MATLAB? (p. 1-2) Provides an overview of the main features of MATLAB.
MATLAB Documentation (p. 1-4) Describes the MATLAB documentation, including online and printed user guides and reference materials.
What Is MATLAB?

MATLAB® is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar noninteractive language such as C or Fortran.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most users of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M-files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.
The MATLAB System

The MATLAB system consists of five main parts:

Development Environment. This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and Command Window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

The MATLAB Mathematical Function Library. This is a vast collection of computational algorithms ranging from elementary functions like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigenvalues, Bessel functions, and fast Fourier transforms.

The MATLAB Language. This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create complete large and complex application programs.

Graphics. MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API). This is a library that allows you to write C and Fortran programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.
MATLAB provides extensive documentation, in both printed and online format, to help you learn about and use all of its features. If you are a new user, start with this book, Getting Started with MATLAB, which introduces you to MATLAB. It covers all the primary MATLAB features at a high level, including many examples to help you to learn the material quickly:

- Chapter 2, “Development Environment”—Introduces the MATLAB development environment, including information about tools and the MATLAB desktop.
- Chapter 3, “Manipulating Matrices”—Introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.
- Chapter 4, “Graphics”—Introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.
- Chapter 5, “Programming with MATLAB”—Describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays. This section also provides an overview of the demo programs included with MATLAB.

To find more detailed information about any of these topics, use the MATLAB online help. The online help provides task-oriented and reference information about MATLAB features. The MATLAB documentation is also available in printed form and in PDF format.

MATLAB Online Help
To view the online documentation, select MATLAB Help from the Help menu in MATLAB. For more information about using the online documentation, see “Help Browser” on page 2-7.

For MATLAB, the documentation is organized into these main topics:

- Development Environment—Provides complete information on the MATLAB desktop.
- Mathematics—Describes how to use MATLAB mathematical and statistical capabilities.
• Programming and Data Types—Describes how to create scripts and functions using the MATLAB language.

• Graphics—Describes how to plot your data using MATLAB graphics capabilities.

• 3-D Visualization—Introduces how to use views, lighting, and transparency to achieve more complex graphic effects than can be achieved using the basic plotting functions.

• Creating Graphical User Interfaces—Describes how to use MATLAB graphical user interface layout tools.

• External Interfaces/API—Describes MATLAB interfaces to C and Fortran programs, Java classes and objects, COM objects, data files, serial port I/O, and DDE.

In addition to the above documentation, MATLAB documentation includes the following reference material:

• Functions - By Category—Lists all the core MATLAB functions. Each function has a reference page that provides the syntax, description, mathematical algorithm (where appropriate), and related functions. You can also access any function reference page using the “Functions - Alphabetical List”.

• Handle Graphics Property Browser—Enables you to easily access descriptions of graphics object properties. For more information about MATLAB graphics, see “Handle Graphics” on page 4-26.

• External Interfaces/API Reference—Covers those functions used by the MATLAB external interfaces, providing information on syntax in the calling language, description, arguments, return values, and examples.

MATLAB online documentation also includes

• Examples—An index of major examples included in the documentation.

• Release Notes—Introduces new features and identifies known problems in the current release.

• Printable Documentation—Provides access to the PDF versions of the documentation, which are suitable for printing.
Development Environment

The Development Environment covers starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files, including the MATLAB desktop. For more information about the topics covered here, see the corresponding topics in “Development Environment”, which is available in the online as well as in the printed manual, *Using MATLAB*.

Starting and Quitting MATLAB (p. 2-2) Start and quit MATLAB and perform operations upon startup and shutdown.

MATLAB Desktop (p. 2-3) The graphical user interface to MATLAB.

Desktop Tools (p. 2-5) Use the Command Window for running functions and entering variables, Start button for launching tools, demos, and documentation, Help browser for accessing documentation, Current Directory browser for accessing files, Workspace browser for viewing variables, Editor/Debugger for modifying MATLAB program files (M-files), and Profiler for optimizing M-file performance.

Other Development Environment Features (p. 2-16) Import and export data, improve M-file performance, interface with source control systems, and access MATLAB from Microsoft Word using the MATLAB Notebook feature.
Starting and Quitting MATLAB

Starting MATLAB
On Windows platforms, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.

On UNIX platforms, to start MATLAB, type `matlab` at the operating system prompt.

After starting MATLAB, the MATLAB desktop opens—see “MATLAB Desktop” on page 2-3.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations. For more information, see the documentation for starting MATLAB.

Quitting MATLAB
To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type `quit` in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a `finish.m` script.
MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.

The first time MATLAB starts, the desktop appears as shown in the following illustration.
You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. Use the **View** menu to open or close the tools. You can also move tools outside the desktop or move them back into the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting **Preferences** from the **File** menu. For example, you can specify the font characteristics for Command Window text. For more information, click the **Help** button in the **Preferences** dialog box.
Desktop Tools

This section provides an introduction to the MATLAB desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are

- “Command Window”
- “Command History”
- “Start Button and Launch Pad”
- “Help Browser”
- “Current Directory Browser”
- “Workspace Browser”
- “Array Editor”
- “Editor/Debugger”
- “Profiler”

Command Window

Use the Command Window to enter variables and run functions and M-files. For more information on controlling input and output, see “Controlling Command Window Input and Output” on page 3-28.
Command History

Statements you enter in the Command Window are logged in the Command History. In the Command History, you can view previously run statements, and copy and execute selected statements.

To save the input and output from a MATLAB session to a file, use the `diary` function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character `!` is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,

```
!emacs magik.m
```

invokes an editor called `emacs` for a file named `magik.m`. When you quit the external program, the operating system returns control to MATLAB.
**Start Button and Launch Pad**

The MATLAB Start button provides easy access to tools, demos, and documentation. Just click the button to see the options.

The Launch Pad provides similar access in a tree view.

**Help Browser**

Use the Help browser to search and view documentation and demos for all your MathWorks products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.
To open the Help browser, click the help button \( \text{\textcircled{2}} \) in the toolbar, or type `helpbrowser` in the Command Window.

The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.
Help Navigator

Use the Help Navigator to find information. It includes

- **Product filter**—Set the filter to show documentation only for the products you specify.
- **Contents** tab—View the titles and tables of contents of documentation for your products.
- **Index** tab—Find specific index entries (selected keywords) in the MathWorks documentation for your products.
- **Demos** tab—View and run demonstrations for your MathWorks products.
- **Search** tab—Look for a specific word or phrase in the documentation. To get help for a specific function, set the **Search type** to **Function Name**.
- **Favorites** tab—View a list of links to documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can

- **Browse to other pages**—Use the arrows at the tops and bottoms of the pages to move through the document, or use the back and forward buttons in the toolbar to go to previously viewed pages.
- **Bookmark pages**—Click the **Add to Favorites** button in the toolbar.
- **Print pages**—Click the print button in the toolbar.
- **Find a term in the page**—Type a term in the **Find in page** field in the toolbar and click **Go**.

Other features available in the display pane are copying information, evaluating a selection, and viewing Web pages.
For More Help
In addition to the Help browser, you can use help functions. To get help for a specific function, use doc. For example, doc format displays documentation for the format function in the Help browser. If you type help followed by the function name, a briefer form of the documentation appears in the Command Window. Other means for getting help include contacting Technical Support (http://www.mathworks.com/support) and participating in the newsgroup for MATLAB users, comp.soft-sys.matlab.

Current Directory Browser
MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

A quick way to view or change the current directory is by using the Current Directory field in the desktop toolbar as shown below.

![Current Directory Field](image)

To search for, view, open, and make changes to MATLAB-related directories and files, use the MATLAB Current Directory browser. Alternatively, you can use the functions dir, cd, and delete.
Search Path

MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. Add the directories containing files you create to the MATLAB search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

To see which directories are on the search path or to change the search path, select Set Path from the File menu in the desktop, and use the Set Path dialog box. Alternatively, you can use the path function to view the search path, addpath to add directories to the path, and rmpath to remove directories from the path.
Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions `who` and `whos`.

To delete variables from the workspace, select the variable and select **Delete** from the **Edit** menu. Alternatively, use the `clear` function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select **Save Workspace As** from the **File** menu, or use the `save` function. This saves the workspace to a binary file called a MAT-file, which has a `.mat` extension. There are options for saving to different formats. To read in a MAT-file, select **Import Data** from the **File** menu, or use the `load` function.

Array Editor

Double-click a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or
two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Change values of array elements.  

Change the display format. 

Use the tabs to view the variables you have open in the Array Editor.
Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.
Profiler
MATLAB includes a graphical user interface, the Profiler, to help you improve the performance of your M-files.

1 Type profile viewer to open the
2 Enter statement to
3 Click Start

Improving M-File Performance - the Profiler

One way to improve the performance of your M-files is to profile them. MATLAB provides an M-file profiler that lets you see how much computation time each line of an M-file uses.

For details on how to use the Profiler, see the Profiler documentation.

For more information, see “Maximizing Performance” in the MATLAB documentation.
Other Development Environment Features

Additional development environment features are

- Importing and Exporting Data—Techniques for bringing data created by other applications into the MATLAB workspace, including the Import Wizard, and packaging MATLAB workspace variables for use by other applications.
- Interfacing with Source Control Systems—Access your source control system from within MATLAB, Simulink®, and Stateflow®.
- Using Notebook—Access MATLAB numeric computation and visualization software from within a word processing environment (Microsoft Word).
Manipulating Matrices

This section provides an introduction to matrix operations in MATLAB.

Matrices and Magic Squares (p. 3-2) Enter matrices, perform matrix operations, and access matrix elements.

Expressions (p. 3-10) Work with variables, numbers, operators, functions, expressions.

Working with Matrices (p. 3-14) Generating matrices, load matrices, create matrices from M-files and concatenation, and delete matrix rows and columns.

More About Matrices and Arrays (p. 3-18) Use matrices for linear algebra, work with arrays, multivariate data, scalar expansion, and logical subscripting, and use the find function.

Controlling Command Window Input and Output (p. 3-28) Change output format, suppress output, enter long lines, and edit at the command line.
Matrices and Magic Squares

In MATLAB, a matrix is a rectangular array of numbers. Special meaning is sometimes attached to 1-by-1 matrices, which are scalars, and to matrices with only one row or column, which are vectors. MATLAB has other ways of storing both numeric and nonnumeric data, but in the beginning, it is usually best to think of everything as a matrix. The operations in MATLAB are designed to be as natural as possible. Where other programming languages work with numbers one at a time, MATLAB allows you to work with entire matrices quickly and easily. A good example matrix, used throughout this book, appears in the Renaissance engraving Melencolia I by the German artist and amateur mathematician Albrecht Dürer.
This image is filled with mathematical symbolism, and if you look carefully, you will see a matrix in the upper right corner. This matrix is known as a magic square and was believed by many in Dürer's time to have genuinely magical properties. It does turn out to have some fascinating characteristics worth exploring.

**Entering Matrices**

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer’s matrix as a list of its elements. You only have to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].
To enter Dürer's matrix, simply type in the Command Window
\[ A = \begin{bmatrix} 16 & 3 & 2 & 13 \\ 5 & 10 & 11 & 8 \\ 9 & 6 & 7 & 12 \\ 4 & 15 & 14 & 1 \end{bmatrix} \]
MATLAB displays the matrix you just entered.
\[ A = \begin{bmatrix} 16 & 3 & 2 & 13 \\ 5 & 10 & 11 & 8 \\ 9 & 6 & 7 & 12 \\ 4 & 15 & 14 & 1 \end{bmatrix} \]
This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as \( A \). Now that you have \( A \) in the workspace, take a look at what makes it so interesting. Why is it magic?

**sum, transpose, and diag**

You are probably already aware that the special properties of a magic square have to do with the various ways of summing its elements. If you take the sum along any row or column, or along either of the two main diagonals, you will always get the same number. Let us verify that using MATLAB. The first statement to try is

\[ \text{sum}(A) \]
MATLAB replies with
\[ \text{ans} = \begin{bmatrix} 34 & 34 & 34 & 34 \end{bmatrix} \]
When you do not specify an output variable, MATLAB uses the variable \( \text{ans} \), short for *answer*, to store the results of a calculation. You have computed a row vector containing the sums of the columns of \( A \). Sure enough, each of the columns has the same sum, the *magic* sum, 34.

How about the row sums? MATLAB has a preference for working with the columns of a matrix, so the easiest way to get the row sums is to transpose the matrix, compute the column sums of the transpose, and then transpose the result. The transpose operation is denoted by an apostrophe or single quote, \( ' \). It flips a matrix about its main diagonal and it turns a row vector into a column vector.
So

\[ A' \]

produces

\[
\begin{bmatrix}
16 & 5 & 9 & 4 \\
3 & 10 & 6 & 15 \\
2 & 11 & 7 & 14 \\
13 & 8 & 12 & 1
\end{bmatrix}
\]

And

\[ \text{sum}(A')' \]

produces a column vector containing the row sums

\[
\begin{bmatrix}
34 \\
34 \\
34 \\
34 \\
34
\end{bmatrix}
\]

The sum of the elements on the main diagonal is obtained with the \texttt{sum} and the \texttt{diag} functions.

\[ \text{diag}(A) \]

produces

\[
\begin{bmatrix}
16 \\
10 \\
7 \\
1
\end{bmatrix}
\]

and

\[ \text{sum(diag(A))} \]

produces

\[
\begin{bmatrix}
34
\end{bmatrix}
\]
The other diagonal, the so-called antidiagonal, is not so important mathematically, so MATLAB does not have a ready-made function for it. But a function originally intended for use in graphics, `fliplr`, flips a matrix from left to right.

\[
\text{sum(diag(fliplr(A)))}
\]
\[
\text{ans = 34}
\]

You have verified that the matrix in Dürer's engraving is indeed a magic square and, in the process, have sampled a few MATLAB matrix operations. The following sections continue to use this matrix to illustrate additional MATLAB capabilities.

**Subscripts**

The element in row \( i \) and column \( j \) of \( A \) is denoted by \( A(i,j) \). For example, \( A(4,2) \) is the number in the fourth row and second column. For our magic square, \( A(4,2) \) is 15. So to compute the sum of the elements in the fourth column of \( A \), type

\[
A(1,4) + A(2,4) + A(3,4) + A(4,4)
\]

This produces

\[
\text{ans = 34}
\]

but is not the most elegant way of summing a single column.

It is also possible to refer to the elements of a matrix with a single subscript, \( A(k) \). This is the usual way of referencing row and column vectors. But it can also apply to a fully two-dimensional matrix, in which case the array is regarded as one long column vector formed from the columns of the original matrix. So, for our magic square, \( A(8) \) is another way of referring to the value 15 stored in \( A(4,2) \).

If you try to use the value of an element outside of the matrix, it is an error.

\[
t = A(4,5)
\]

Index exceeds matrix dimensions.
On the other hand, if you store a value in an element outside of the matrix, the size increases to accommodate the newcomer.

\[
X = A;
X(4,5) = 17
\]

\[
X = \\
16 \ 3 \ 2 \ 13 \ 0 \\
5 \ 10 \ 11 \ 8 \ 0 \\
9 \ 6 \ 7 \ 12 \ 0 \\
4 \ 15 \ 14 \ 1 \ 17
\]

**The Colon Operator**

The colon, `:`, is one of the most important MATLAB operators. It occurs in several different forms. The expression

\[
1:10
\]

is a row vector containing the integers from 1 to 10

\[
1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8 \ 9 \ 10
\]

To obtain nonunit spacing, specify an increment. For example,

\[
100:-7:50
\]

is

\[
100 \ 93 \ 86 \ 79 \ 72 \ 65 \ 58 \ 51
\]

and

\[
0:\text{pi/4:pi}
\]

is

\[
0 \ 0.7854 \ 1.5708 \ 2.3562 \ 3.1416
\]

Subscript expressions involving colons refer to portions of a matrix.

\[
A(1:k,j)
\]

is the first \( k \) elements of the \( j \)th column of \( A \). So

\[
\text{sum}(A(1:4,4))
\]
computes the sum of the fourth column. But there is a better way. The colon by itself refers to all the elements in a row or column of a matrix and the keyword end refers to the last row or column. So

```matlab
sum(A(:,end))
```
computes the sum of the elements in the last column of A.

```matlab
ans =
34
```

Why is the magic sum for a 4-by-4 square equal to 34? If the integers from 1 to 16 are sorted into four groups with equal sums, that sum must be

```matlab
sum(1:16)/4
```

which, of course, is

```matlab
ans =
34
```

**The magic Function**

MATLAB actually has a built-in function that creates magic squares of almost any size. Not surprisingly, this function is named `magic`.

```matlab
B = magic(4)
```

```matlab
B =
16  2  3 13
 5 11 10  8
 9  7  6 12
 4 14 15  1
```

This matrix is almost the same as the one in the Dürer engraving and has all the same “magic” properties; the only difference is that the two middle columns are exchanged.

To make this B into Dürer’s A, swap the two middle columns.

```matlab
A = B(:,[1 3 2 4])
```
This says, for each of the rows of matrix $B$, reorder the elements in the order 1, 3, 2, 4. It produces

$$A = \begin{bmatrix} 16 & 3 & 2 & 13 \\ 5 & 10 & 11 & 8 \\ 9 & 6 & 7 & 12 \\ 4 & 15 & 14 & 1 \end{bmatrix}$$

Why would Dürer go to the trouble of rearranging the columns when he could have used MATLAB ordering? No doubt he wanted to include the date of the engraving, 1514, at the bottom of his magic square.
Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are

- “Variables” on page 3-10
- “Numbers” on page 3-10
- “Operators” on page 3-11
- “Functions” on page 3-11

See also, “Examples of Expressions” on page 3-13.

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

\[
\text{num\_students} = 25
\]

creates a 1-by-1 matrix named \text{num\_students} and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

\[
\begin{array}{ccc}
3 & -99 & 0.0001 \\
9.6397238 & 1.60210e-20 & 6.02252e23 \\
1i & -3.14159j & 3e5i \\
\end{array}
\]
All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly $10^{-308}$ to $10^{+308}$.

**Operators**
Expressions use familiar arithmetic operators and precedence rules.

- Addition
- Subtraction
- Multiplication
- Division
- Left division (described in “Matrices and Linear Algebra” in the MATLAB documentation)
- Power
- Complex conjugate transpose

**Functions**
MATLAB provides a large number of standard elementary mathematical functions, including `abs`, `sqrt`, `exp`, and `sin`. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type

```
help elfun
```

For a list of more advanced mathematical and matrix functions, type

```
help specfun
help elmat
```
Some of the functions, like `sqrt` and `sin`, are built in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like `gamma` and `sinh`, are implemented in M-files. You can see the code and even modify it if you want.

Several special functions provide values of useful constants.

- `pi` 3.14159265...
- `i` Imaginary unit, $\sqrt{-1}$
- `j` Same as `i`
- `eps` Floating-point relative precision, $2^{-52}$
- `realmin` Smallest floating-point number, $2^{-1022}$
- `realmax` Largest floating-point number, $(2^{-\varepsilon})2^{1023}$
- `Inf` Infinity
- `NaN` Not-a-number

Infinity is generated by dividing a nonzero value by zero, or by evaluating well defined mathematical expressions that overflow, i.e., exceed `realmax`. Not-a-number is generated by trying to evaluate expressions like $0/0$ or $\text{Inf} - \text{Inf}$ that do not have well defined mathematical values.

The function names are not reserved. It is possible to overwrite any of them with a new variable, such as

```matlab
eps = 1.e-6
```

and then use that value in subsequent calculations. The original function can be restored with

```matlab
clear eps
```
Examples of Expressions
You have already seen several examples of MATLAB expressions. Here are a few more examples, and the resulting values.

\[
\rho = \frac{1 + \sqrt{5}}{2}
\]
\[
\rho = 1.6180
\]

\[
a = \text{abs}(3 + 4i)
a = 5
\]

\[
z = \sqrt{\text{besselk}(4/3, \rho - i)}
z = 0.3730 + 0.3214i
\]

\[
\text{huge} = \exp(\log(\text{realmax}))
\]
\[
\text{huge} = 1.7977e+308
\]

\[
\text{toobig} = \pi \times \text{huge}
\]
\[
\text{toobig} = \text{Inf}
\]
Working with Matrices

This section introduces you to other ways of creating matrices:

- “Generating Matrices” on page 3-14
- “The load Function” on page 3-15
- “M-Files” on page 3-15
- “Concatenation” on page 3-16
- “Deleting Rows and Columns” on page 3-17

Generating Matrices

MATLAB provides four functions that generate basic matrices.

- `zeros` All zeros
- `ones` All ones
- `rand` Uniformly distributed random elements
- `randn` Normally distributed random elements

Here are some examples.

```
z = zeros(2,4)
z =
  0   0   0   0
  0   0   0   0

F = 5*ones(3,3)
F =
  5   5   5
  5   5   5
  5   5   5

N = fix(10*rand(1,10))
N =
  4   9   4   4   8   5   2   6   8   0

R = randn(4,4)
```
R =

\[
\begin{bmatrix}
1.0668 & 0.2944 & -0.6918 & -1.4410 \\
0.0593 & -1.3362 & 0.8580 & 0.5711 \\
-0.0956 & 0.7143 & 1.2540 & -0.3999 \\
-0.8323 & 1.6236 & -1.5937 & 0.6900
\end{bmatrix}
\]

The load Function

The `load` function reads binary files containing matrices generated by earlier MATLAB sessions, or reads text files containing numeric data. The text file should be organized as a rectangular table of numbers, separated by blanks, with one row per line, and an equal number of elements in each row. For example, outside of MATLAB, create a text file containing these four lines.

\[
\begin{align*}
16.0 & & 3.0 & & 2.0 & & 13.0 \\
5.0 & & 10.0 & & 11.0 & & 8.0 \\
9.0 & & 6.0 & & 7.0 & & 12.0 \\
4.0 & & 15.0 & & 14.0 & & 1.0
\end{align*}
\]

Store the file under the name `magik.dat`. Then the statement

```matlab
load magik.dat
```

reads the file and creates a variable, `magik`, containing our example matrix.

An easy way to read data into MATLAB in many text or binary formats is to use Import Wizard.

M-Files

You can create your own matrices using `M-files`, which are text files containing MATLAB code. Use the MATLAB Editor or another text editor to create a file containing the same statements you would type at the MATLAB command line. Save the file under a name that ends in `.m`.

For example, create a file containing these five lines.

```matlab
A = [ ... 
16.0 3.0 2.0 13.0 \\
5.0 10.0 11.0 8.0 \\
9.0 6.0 7.0 12.0 \\
4.0 15.0 14.0 1.0 ];
```
Store the file under the name `magik.m`. Then the statement

```matlab
magik
```

reads the file and creates a variable, `A`, containing our example matrix.

**Concatenation**

*Concatenation* is the process of joining small matrices to make bigger ones. In fact, you made your first matrix by concatenating its individual elements. The pair of square brackets, `[]`, is the concatenation operator. For an example, start with the 4-by-4 magic square, `A`, and form

```matlab
B = [A  A+32; A+48  A+16]  
```

The result is an 8-by-8 matrix, obtained by joining the four submatrices.

```matlab
B =  
    16    3    2   13    48    35    34    45  
    5   10   11    8    37    42    43    40  
    9    6    7   12    41    38    39    44  
    4   15   14    1    36    47    46    33  
   64   51   50   61    32    19    18    29  
   53   58   59   56    21    26    27    24  
   57   54   55   60    25    22    23    28  
   52   63   62    49    20    31    30    17  
```

This matrix is halfway to being another magic square. Its elements are a rearrangement of the integers `1:64`. Its column sums are the correct value for an 8-by-8 magic square.

```matlab
g = sum(B)  
ans =  
    260    260    260    260    260    260    260    260  
```

But its row sums, `sum(B')`, are not all the same. Further manipulation is necessary to make this a valid 8-by-8 magic square.
Deleting Rows and Columns
You can delete rows and columns from a matrix using just a pair of square brackets. Start with

\[ X = A; \]

Then, to delete the second column of \( X \), use

\[ X(:,2) = [] \]

This changes \( X \) to

\[
X = \\
16 & 2 & 13 \\
5 & 11 & 8 \\
9 & 7 & 12 \\
4 & 14 & 1 \\
\]

If you delete a single element from a matrix, the result is not a matrix anymore. So, expressions like

\[ X(1,2) = [] \]

result in an error. However, using a single subscript deletes a single element, or sequence of elements, and reshapes the remaining elements into a row vector. So

\[ X(2:2:10) = [] \]

results in

\[
X = \\
16 & 9 & 2 & 7 & 13 & 12 & 1 \\
\]
More About Matrices and Arrays

This section shows you more about working with matrices and arrays, focusing on

- “Linear Algebra” on page 3-18
- “Arrays” on page 3-21
- “Multivariate Data” on page 3-24
- “Scalar Expansion” on page 3-25
- “Logical Subscripting” on page 3-26
- “The find Function” on page 3-27

Linear Algebra

Informally, the terms matrix and array are often used interchangeably. More precisely, a matrix is a two-dimensional numeric array that represents a linear transformation. The mathematical operations defined on matrices are the subject of linear algebra.

Dürer’s magic square

\[
A = \begin{pmatrix}
16 & 3 & 2 & 13 \\
5 & 10 & 11 & 8 \\
9 & 6 & 7 & 12 \\
4 & 15 & 14 & 1
\end{pmatrix}
\]

provides several examples that give a taste of MATLAB matrix operations. You have already seen the matrix transpose, \(A'\). Adding a matrix to its transpose produces a symmetric matrix.

\[
A + A' = \begin{pmatrix}
32 & 8 & 11 & 17 \\
8 & 20 & 17 & 23 \\
11 & 17 & 14 & 26 \\
17 & 23 & 26 & 2
\end{pmatrix}
\]
The multiplication symbol, *, denotes the matrix multiplication involving inner products between rows and columns. Multiplying the transpose of a matrix by the original matrix also produces a symmetric matrix.

\[ A^* A \]

\[
\begin{bmatrix}
378 & 212 & 206 & 360 \\
212 & 370 & 368 & 206 \\
206 & 368 & 370 & 212 \\
360 & 206 & 212 & 378 \\
\end{bmatrix}
\]

The determinant of this particular matrix happens to be zero, indicating that the matrix is singular.

\[ d = \text{det}(A) \]

\[ d = 0 \]

The reduced row echelon form of \( A \) is not the identity.

\[ R = \text{rref}(A) \]

\[
\begin{bmatrix}
1 & 0 & 0 & 1 \\
0 & 1 & 0 & -3 \\
0 & 0 & 1 & 3 \\
0 & 0 & 0 & 0 \\
\end{bmatrix}
\]

Since the matrix is singular, it does not have an inverse. If you try to compute the inverse with

\[ X = \text{inv}(A) \]

you will get a warning message

Warning: Matrix is close to singular or badly scaled. 
Results may be inaccurate. RCOND = 1.175530e-017.

Roundoff error has prevented the matrix inversion algorithm from detecting exact singularity. But the value of rcond, which stands for reciprocal condition estimate, is on the order of eps, the floating-point relative precision, so the computed inverse is unlikely to be of much use.
The eigenvalues of the magic square are interesting.

\[ e = \text{eig}(A) \]

\[ e = \]

\[
34.0000 \\
8.0000 \\
0.0000 \\
-8.0000
\]

One of the eigenvalues is zero, which is another consequence of singularity. The largest eigenvalue is 34, the magic sum. That is because the vector of all ones is an eigenvector.

\[ v = \text{ones}(4,1) \]

\[ v = \]

\[
1 \\
1 \\
1 \\
1
\]

\[ A \cdot v \]

\[ \text{ans} = \]

\[
34 \\
34 \\
34 \\
34
\]

When a magic square is scaled by its magic sum,

\[ P = A/34 \]

the result is a *doubly stochastic* matrix whose row and column sums are all 1.

\[ P = \]

\[
0.4706 \quad 0.0882 \quad 0.0588 \quad 0.3824 \\
0.1471 \quad 0.2941 \quad 0.3235 \quad 0.2353 \\
0.2647 \quad 0.1765 \quad 0.2059 \quad 0.3529 \\
0.1176 \quad 0.4412 \quad 0.4118 \quad 0.0294
\]
Such matrices represent the transition probabilities in a *Markov process*. Repeated powers of the matrix represent repeated steps of the process. For our example, the fifth power

\[ P^5 \]

is

\[
\begin{bmatrix}
0.2507 & 0.2495 & 0.2494 & 0.2504 \\
0.2497 & 0.2501 & 0.2502 & 0.2500 \\
0.2500 & 0.2498 & 0.2499 & 0.2503 \\
0.2496 & 0.2506 & 0.2505 & 0.2493
\end{bmatrix}
\]

This shows that as \( k \) approaches infinity, all the elements in the \( k \)th power, \( P^k \), approach \( \frac{1}{4} \).

Finally, the coefficients in the characteristic polynomial

\[ \text{poly}(A) \]

are

\[
1 \quad -34 \quad -64 \quad 2176 \quad 0
\]

This indicates that the characteristic polynomial

\[ \det(A - \lambda I) \]

is

\[
\lambda^4 - 34\lambda^3 - 64\lambda^2 + 2176\lambda
\]

The constant term is zero, because the matrix is singular, and the coefficient of the cubic term is -34, because the matrix is magic!

**Arrays**

When they are taken away from the world of linear algebra, matrices become two-dimensional numeric arrays. Arithmetic operations on arrays are done element-by-element. This means that addition and subtraction are the same for arrays and matrices, but that multiplicative operations are different. MATLAB uses a dot, or decimal point, as part of the notation for multiplicative array operations.
The list of operators includes

+  Addition
-  Subtraction
.*  Element-by-element multiplication
./  Element-by-element division
.  Element-by-element left division
.^  Element-by-element power
.'  Unconjugated array transpose

If the Dürer magic square is multiplied by itself with array multiplication

A.*A

d the result is an array containing the squares of the integers from 1 to 16, in an
unusual order.

ans =
    256     9     4    169
     25    100   121     64
     81    36     49    144
     16   225   196     1

Building Tables

Array operations are useful for building tables. Suppose \( n \) is the column vector

\[ n = (0:9)'; \]

Then

\[ pows = [n \ n.^2 \ 2.^n] \]
builds a table of squares and powers of 2.

\[
pows =
\begin{array}{ccc}
0 & 0 & 1 \\
1 & 1 & 2 \\
2 & 4 & 4 \\
3 & 9 & 8 \\
4 & 16 & 16 \\
5 & 25 & 32 \\
6 & 36 & 64 \\
7 & 49 & 128 \\
8 & 64 & 256 \\
9 & 81 & 512 \\
\end{array}
\]

The elementary math functions operate on arrays element by element. So

\[
\text{format short g}
\]
\[
x = (1:0.1:2)';
\]
\[
\log = [x \ \log10(x)]
\]

builds a table of logarithms.

\[
\log =
\begin{array}{ccc}
1.0 & 0 \\
1.1 & 0.04139 \\
1.2 & 0.07918 \\
1.3 & 0.11394 \\
1.4 & 0.14613 \\
1.5 & 0.17609 \\
1.6 & 0.20412 \\
1.7 & 0.23045 \\
1.8 & 0.25527 \\
1.9 & 0.27875 \\
2.0 & 0.30103 \\
\end{array}
\]
Multivariate Data

MATLAB uses column-oriented analysis for multivariate statistical data. Each column in a data set represents a variable and each row an observation. The \((i, j)\)th element is the \(i\)th observation of the \(j\)th variable.

As an example, consider a data set with three variables:

- Heart rate
- Weight
- Hours of exercise per week

For five observations, the resulting array might look like

\[
D = \begin{bmatrix}
72 & 134 & 3.2 \\
81 & 201 & 3.5 \\
69 & 156 & 7.1 \\
82 & 148 & 2.4 \\
75 & 170 & 1.2 \\
\end{bmatrix}
\]

The first row contains the heart rate, weight, and exercise hours for patient 1, the second row contains the data for patient 2, and so on. Now you can apply many MATLAB data analysis functions to this data set. For example, to obtain the mean and standard deviation of each column

\[
\mu = \text{mean}(D), \quad \sigma = \text{std}(D)
\]

\[
\mu = \begin{bmatrix}
75.8 & 161.8 & 3.48 \\
\end{bmatrix}
\]

\[
\sigma = \begin{bmatrix}
5.6303 & 25.499 & 2.2107 \\
\end{bmatrix}
\]

For a list of the data analysis functions available in MATLAB, type

\[
\text{help datafun}
\]

If you have access to the Statistics Toolbox, type

\[
\text{help stats}
\]
Scalar Expansion

Matrices and scalars can be combined in several different ways. For example, a scalar is subtracted from a matrix by subtracting it from each element. The average value of the elements in our magic square is 8.5, so

\[ B = A - 8.5 \]

forms a matrix whose column sums are zero.

\[ B = \begin{bmatrix} 7.5 & -5.5 & -6.5 & 4.5 \\ -3.5 & 1.5 & 2.5 & -0.5 \\ 0.5 & -2.5 & -1.5 & 3.5 \\ -4.5 & 6.5 & 5.5 & -7.5 \end{bmatrix} \]

\[ \text{sum}(B) \]

\[ \text{ans} = \begin{bmatrix} 0 & 0 & 0 & 0 \end{bmatrix} \]

With scalar expansion, MATLAB assigns a specified scalar to all indices in a range. For example,

\[ B(1:2,2:3) = 0 \]

zeroes out a portion of \( B \).

\[ B = \begin{bmatrix} 7.5 & 0 & 0 & 4.5 \\ -3.5 & 0 & 0 & -0.5 \\ 0.5 & -2.5 & -1.5 & 3.5 \\ -4.5 & 6.5 & 5.5 & -7.5 \end{bmatrix} \]
Logical Subscripting

The logical vectors created from logical and relational operations can be used to reference subarrays. Suppose $X$ is an ordinary matrix and $L$ is a matrix of the same size that is the result of some logical operation. Then $X(L)$ specifies the elements of $X$ where the elements of $L$ are nonzero.

This kind of subscripting can be done in one step by specifying the logical operation as the subscripting expression. Suppose you have the following set of data.

$$x = \begin{bmatrix} 2.1 & 1.7 & 1.6 & 1.5 & \text{NaN} & 1.9 & 1.8 & 1.5 & 5.1 & 1.8 & 1.4 & 2.2 & 1.6 & 1.8 \end{bmatrix}$$

The NaN is a marker for a missing observation, such as a failure to respond to an item on a questionnaire. To remove the missing data with logical indexing, use $\text{finite}(x)$, which is true for all finite numerical values and false for NaN and Inf.

$$x = x(\text{finite}(x))$$

$$x = \begin{bmatrix} 2.1 & 1.7 & 1.6 & 1.5 & 1.9 & 1.8 & 1.5 & 5.1 & 1.8 & 1.4 & 2.2 & 1.6 & 1.8 \end{bmatrix}$$

Now there is one observation, 5.1, which seems to be very different from the others. It is an outlier. The following statement removes outliers, in this case those elements more than three standard deviations from the mean.

$$x = x(\text{abs}(x - \text{mean}(x)) \leq 3 \times \text{std}(x))$$

$$x = \begin{bmatrix} 2.1 & 1.7 & 1.6 & 1.5 & 1.9 & 1.8 & 1.5 & 1.8 & 1.4 & 2.2 & 1.6 & 1.8 \end{bmatrix}$$

For another example, highlight the location of the prime numbers in Dürer’s magic square by using logical indexing and scalar expansion to set the nonprimes to 0.

$$A(\neg \text{isprime}(A)) = 0$$

$$A = \begin{bmatrix} 0 & 3 & 2 & 13 \\ 5 & 0 & 11 & 0 \\ 0 & 0 & 7 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$
The find Function

The find function determines the indices of array elements that meet a given logical condition. In its simplest form, find returns a column vector of indices. Transpose that vector to obtain a row vector of indices. For example,

```matlab
k = find(isprime(A))'
```

picks out the locations, using one-dimensional indexing, of the primes in the magic square.

```matlab
k =
    2     5     9    10    11    13
```

Display those primes, as a row vector in the order determined by k, with

```matlab
A(k)
```

```matlab
ans =
    5     3     2   11     7    13
```

When you use k as a left-hand-side index in an assignment statement, the matrix structure is preserved.

```matlab
A(k) = NaN
```

```matlab
A =
    16   NaN   NaN   NaN
    NaN    10   NaN     8
    9     6   NaN    12
    4    15    14     1
```
Controlling Command Window Input and Output

So far, you have been using the MATLAB command line, typing functions and expressions, and seeing the results printed in the Command Window. This section describes

- “The format Function” on page 3-28, to control the appearance of the output values
- “Suppressing Output” on page 3-30
- “Entering Long Statements” on page 3-30
- “Command Line Editing” on page 3-30

The format Function

The `format` function controls the numeric format of the values displayed by MATLAB. The function affects only how numbers are displayed, not how MATLAB computes or saves them. Here are the different formats, together with the resulting output produced from a vector `x` with components of different magnitudes.

Note  To ensure proper spacing, use a fixed-width font, such as Courier.

```
x = [4/3 1.2345e-6]
format short
    1.3333    0.0000
format short e
    1.3333e+000   1.2345e-006
format short g
    1.3333   1.2345e-006
```
format long

1.33333333333333 0.00000123450000

format long e

1.333333333333333e+000 1.234500000000000e-006

format long g

1.33333333333333 1.2345e-006

format bank

1.33 0.00

format rat

4/3 1/810045

format hex

3ff5555555555555 3eb4b6231abfd271

If the largest element of a matrix is larger than $10^3$ or smaller than $10^{-3}$, MATLAB applies a common scale factor for the short and long formats.

In addition to the `format` functions shown above

format compact

suppresses many of the blank lines that appear in the output. This lets you view more information on a screen or window. If you want more control over the output format, use the `sprintf` and `fprintf` functions.
Suppressing Output
If you simply type a statement and press Return or Enter, MATLAB automatically displays the results on screen. However, if you end the line with a semicolon, MATLAB performs the computation but does not display any output. This is particularly useful when you generate large matrices. For example,

\[ A = \text{magic}(100); \]

Entering Long Statements
If a statement does not fit on one line, use an ellipsis (three periods), ..., followed by Return or Enter to indicate that the statement continues on the next line. For example,

\[ s = 1 - 1/2 + 1/3 - 1/4 + 1/5 - 1/6 + 1/7 \ldots - 1/8 + 1/9 - 1/10 + 1/11 - 1/12; \]

Blank spaces around the =, +, and - signs are optional, but they improve readability.

Command Line Editing
Various arrow and control keys on your keyboard allow you to recall, edit, and reuse statements you have typed earlier. For example, suppose you mistakenly enter

\[ \rho = (1 + \text{sqt}(5))/2 \]

You have misspelled sqrt. MATLAB responds with

Undefined function or variable 'sqt'.

Instead of retyping the entire line, simply press the ↑ key. The statement you typed is redisplayed. Use the ← key to move the cursor over and insert the missing r. Repeated use of the ↑ key recalls earlier lines. Typing a few characters and then the ↑ key finds a previous line that begins with those characters. You can also copy previously executed statements from the Command History. For more information, see “Command History” on page 2-6.

Following is the list of arrow and control keys you can use in the Command Window. If the preference you select for Command line key bindings is
Emacs (MATLAB standard), you can also use the Ctrl+key combinations shown. See also general keyboard shortcuts for desktop tools.

<table>
<thead>

Graphics

Basic Plotting (p. 4-2)  Create a plot, include multiple data sets, specify line style, colors, and markers, plot imaginary and complex data, add new plots, work with figure windows and axes, and save figures.

Editing Plots (p. 4-14)  Edit plots interactively and using functions, and use the property editor.

Mesh and Surface Plots (p. 4-18)  Visualize functions of two variables.

Images (p. 4-22)  Work with images.

Printing Graphics (p. 4-24)  Print and export figures.

Handle Graphics (p. 4-26)  Work with graphics objects and set object properties.

Graphics User Interfaces (p. 4-33)  Create graphical user interfaces.

Animations (p. 4-34)  Create moving graphics.
Basic Plotting

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. This section describes a few of the most important graphics functions and provides examples of some typical applications:

- “Creating a Plot” on page 4-2
- “Multiple Data Sets in One Graph” on page 4-3
- “Specifying Line Styles and Colors” on page 4-4
- “Plotting Lines and Markers” on page 4-5
- “Imaginary and Complex Data” on page 4-6
- “Adding Plots to an Existing Graph” on page 4-7
- “Figure Windows” on page 4-8
- “Multiple Plots in One Figure” on page 4-9
- “Controlling the Axes” on page 4-10
- “Axis Labels and Titles” on page 4-12
- “Saving a Figure” on page 4-13

Creating a Plot

The `plot` function has different forms, depending on the input arguments. If `y` is a vector, `plot(y)` produces a piecewise linear graph of the elements of `y` versus the index of the elements of `y`. If you specify two vectors as arguments, `plot(x,y)` produces a graph of `y` versus `x`.

For example, these statements use the `colon` operator to create a vector of `x` values ranging from zero to `2π`, compute the sine of these values, and plot the result.

```matlab
x = 0:pi/100:2*pi;
y = sin(x);
plot(x,y)
```

Now label the axes and add a title. The characters `\pi` create the symbol π.

```matlab
xlabel('x = 0:2\pi')
ylabel('Sine of x')
title('Plot of the Sine Function','FontSize',12)
```
Multiple Data Sets in One Graph

Multiple $x$-$y$ pair arguments create multiple graphs with a single call to `plot`. MATLAB automatically cycles through a predefined (but user settable) list of colors to allow discrimination among sets of data. For example, these statements plot three related functions of $x$, each curve in a separate distinguishing color.

```matlab
y2 = sin(x-.25);
y3 = sin(x-.5);
plot(x,y,x,y2,x,y3)
```

The `legend` command provides an easy way to identify the individual plots.

```matlab
legend('sin(x)', 'sin(x-.25)', 'sin(x-.5)')
```
Specifying Line Styles and Colors

It is possible to specify color, line styles, and markers (such as plus signs or circles) when you plot your data using the `plot` command.

```
plot(x, y, 'color_style_marker')
```

color_style_marker is a string containing from one to four characters (enclosed in single quotation marks) constructed from a color, a line style, and a marker type:

- Color strings are 'c', 'm', 'y', 'r', 'g', 'b', 'w', and 'k'. These correspond to cyan, magenta, yellow, red, green, blue, white, and black.
- Linestyle strings are '-' for solid, '--' for dashed, ':' for dotted, '...' for dash-dot. Omit the linestyle for no line.
• The marker types are ‘+’, ‘o’, ‘*’, and ‘x’ and the filled marker types are ‘s’ for square, ‘d’ for diamond, ‘^’ for up triangle, ‘v’ for down triangle, ‘>’ for right triangle, ‘<’ for left triangle, ‘p’ for pentagram, ‘h’ for hexagram, and none for no marker.

You can also edit color, line style, and markers interactively. See “Editing Plots” on page 4-14 for more information.

**Plotting Lines and Markers**

If you specify a marker type but not a linestyle, MATLAB draws only the marker. For example,

```matlab
plot(x,y,'ks')
```

plots black squares at each data point, but does not connect the markers with a line.

The statement

```matlab
plot(x,y,'r:+')
```

plots a red dotted line and places plus sign markers at each data point. You may want to use fewer data points to plot the markers than you use to plot the lines. This example plots the data twice using a different number of points for the dotted line and marker plots.

```matlab
x1 = 0:pi/100:2*pi;
x2 = 0:pi/10:2*pi;
plot(x1,sin(x1),'r:',x2,sin(x2),'r+')
```
**Imaginary and Complex Data**

When the arguments to `plot` are complex, the imaginary part is ignored *except* when `plot` is given a single complex argument. For this special case, the command is a shortcut for a plot of the real part versus the imaginary part. Therefore,

```matlab
plot(Z)
```

where `Z` is a complex vector or matrix, is equivalent to

```matlab
plot(real(Z), imag(Z))
```

For example,

```matlab
t = 0:pi/10:2*pi;
plot(exp(i*t), '-o')
axis equal
```
draws a 20-sided polygon with little circles at the vertices. The command \texttt{axis equal} makes the individual tick mark increments on the \textit{x}- and \textit{y}-axes the same length, which makes this plot more circular in appearance.

\begin{center}
\includegraphics[width=\textwidth]{plot.png}
\end{center}

**Adding Plots to an Existing Graph**

The \texttt{hold} command enables you to add plots to an existing graph. When you type

\begin{verbatim}
hold on
\end{verbatim}

MATLAB does not replace the existing graph when you issue another plotting command; it adds the new data to the current graph, rescaling the axes if necessary.
For example, these statements first create a contour plot of the peaks function, then superimpose a pseudocolor plot of the same function.

```matlab
[x,y,z] = peaks;
contour(x,y,z,20,'k')
hold on
pcolor(x,y,z)
shading interp
hold off
```

The `hold on` command causes the `pcolor` plot to be combined with the `contour` plot in one figure.

**Figure Windows**

Graphing functions automatically open a new figure window if there are no figure windows already on the screen. If a figure window exists, MATLAB uses that window for graphics output. If there are multiple figure windows open,
MATLAB targets the one that is designated the “current figure” (the last figure used or clicked in).

To make an existing figure window the current figure, you can click the mouse while the pointer is in that window or you can type

\[
\text{figure}(n)
\]

where \( n \) is the number in the figure title bar. The results of subsequent graphics commands are displayed in this window.

To open a new figure window and make it the current figure, type

\[
\text{figure}
\]

**Multiple Plots in One Figure**

The `subplot` command enables you to display multiple plots in the same window or print them on the same piece of paper. Typing

\[
\text{subplot}(m,n,p)
\]

partitions the figure window into an \( m \)-by-\( n \) matrix of small subplots and selects the \( p \)th subplot for the current plot. The plots are numbered along first the top row of the figure window, then the second row, and so on. For example, these statements plot data in four different subregions of the figure window.

\[
\begin{align*}
    t &= 0:2\pi/10:2\pi; \\
    [X,Y,Z] &= \text{cylinder}(4\cos(t)); \\
    \text{subplot}(2,2,1); &\quad \text{mesh}(X) \\
    \text{subplot}(2,2,2); &\quad \text{mesh}(Y) \\
    \text{subplot}(2,2,3); &\quad \text{mesh}(Z) \\
    \text{subplot}(2,2,4); &\quad \text{mesh}(X,Y,Z)
\end{align*}
\]
Controlling the Axes
The `axis` command supports a number of options for setting the scaling, orientation, and aspect ratio of plots. You can also set these options interactively. See “Editing Plots” on page 4-14 for more information.

Setting Axis Limits
By default, MATLAB finds the maxima and minima of the data to choose the axis limits to span this range. The `axis` command enables you to specify your own limits

```
axis([xmin xmax ymin ymax])
```
or for three-dimensional graphs,

\[
\text{axis([xmin xmax ymin ymax zmin zmax])}
\]

Use the command

\[
\text{axis auto}
\]

to reenable MATLAB automatic limit selection.

**Setting Axis Aspect Ratio**

axis also enables you to specify a number of predefined modes. For example,

\[
\text{axis square}
\]

makes the \(x\)-axes and \(y\)-axes the same length.

\[
\text{axis equal}
\]

makes the individual tick mark increments on the \(x\)- and \(y\)-axes the same length. This means

\[
\text{plot(exp(i*[0:pi/10:2*pi]))}
\]

followed by either \text{axis square} or \text{axis equal} turns the oval into a proper circle.

\[
\text{axis auto normal}
\]

returns the axis scaling to its default, automatic mode.

**Setting Axis Visibility**

You can use the axis command to make the axis visible or invisible.

\[
\text{axis on}
\]

makes the axis visible. This is the default.

\[
\text{axis off}
\]

makes the axis invisible.
Setting Grid Lines
The `grid` command toggles grid lines on and off. The statement

```matlab
grid on
```

turns the grid lines on and

```matlab
grid off
```

turns them back off again.

Axis Labels and Titles
The `xlabel`, `ylabel`, and `zlabel` commands add x-, y-, and z-axis labels. The `title` command adds a title at the top of the figure and the `text` function inserts text anywhere in the figure. A subset of TeX notation produces Greek letters. You can also set these options interactively. See “Editing Plots” on page 4-14 for more information.

```matlab
t = -pi:pi/100:pi;
y = sin(t);
plot(t,y)
axis([-pi pi -1 1])
xlabel('-\pi \leq \itt \leq \pi')
ylabel('\sin(t)')
title('Graph of the sine function')
text(1,-1/3,'\it{Note the odd symmetry}.' )
```
**Saving a Figure**

To save a figure, select **Save** from the **File** menu. To save it using a graphics format, such as TIFF, for use with other applications, select **Export** from the **File** menu. You can also save from the command line—use the `saveas` command, including any options to save the figure in a different format.
Editing Plots

MATLAB formats a graph to provide readability, setting the scale of axes, including tick marks on the axes, and using color and line style to distinguish the plots in the graph. However, if you are creating presentation graphics, you may want to change this default formatting or add descriptive labels, titles, legends and other annotations to help explain your data.

MATLAB supports two ways to edit the plots you create.

- Using the mouse to select and edit objects interactively
- Using MATLAB functions at the command-line or in an M-file

Interactive Plot Editing

If you enable plot editing mode in the MATLAB figure window, you can perform point-and-click editing of the objects in your graph. In this mode, you select the object or objects you want to edit by double-clicking it. This starts the Property Editor, which provides access to properties of the object that control its appearance and behavior.

For more information about interactive editing, see “Using Plot Editing Mode” on page 4-15. For information about editing object properties in plot editing mode, see “Using the Property Editor” on page 4-16.

Note  Plot editing mode provides an alternative way to access the properties of MATLAB graphic objects. However, you can only access a subset of object properties through this mechanism. You may need to use a combination of interactive editing and command line editing to achieve the effect you desire.

Using Functions to Edit Graphs

If you prefer to work from the MATLAB command line or if you are creating an M-file, you can use MATLAB commands to edit the graphs you create. Taking advantage of MATLAB Handle Graphics system, you can use the set and get commands to change the properties of the objects in a graph. For more information about using command line, see “Handle Graphics” on page 4-26.
Using Plot Editing Mode
The MATLAB figure window supports a point-and-click style editing mode that you can use to customize the appearance of your graph. The following illustration shows a figure window with plot editing mode enabled and labels the main plot editing mode features.

- Click this button to start plot edit mode.
- Use the Edit, Insert, and Tools menus to add objects or edit existing objects in the graph.
- Double-click an object to select it.
- Position labels, legends, and other objects by clicking and dragging them.
- Access object-specific plot edit functions through context-sensitive pop-up menus.

Use these toolbar buttons to add text, arrows, and lines to a graph.
Using the Property Editor

In plot editing mode, you can use a graphical user interface, called the Property Editor, to edit the properties of objects in the graph. The Property Editor provides access to many properties of the root, figure, axes, line, light, patch, image, surfaces rectangle, and text objects. For example, using the Property Editor, you can change the thickness of a line, add titles and axes labels, add lights, and perform many other plot editing tasks.

This figure shows the components of the Property Editor interface.
Starting the Property Editor

You start the Property Editor by double-clicking an object in a graph, such as a line, or by right-clicking an object and selecting the Properties option from the object’s context menu.

You can also start the Property Editor by selecting either the Figure Properties, Axes Properties, or Current Object Properties from the figure window Edit menu. These options automatically enable plot editing mode, if it is not already enabled.

Once you start the Property Editor, keep it open throughout an editing session. It provides access to all the objects in the graph. If you click another object in the graph, the Property Editor displays the set of panels associated with that object type. You can also use the Property Editor’s navigation bar to select an object in the graph to edit.
Mesh and Surface Plots

MATLAB defines a surface by the $z$-coordinates of points above a grid in the $x$-$y$ plane, using straight lines to connect adjacent points. The `mesh` and `surf` plotting functions display surfaces in three dimensions. `mesh` produces wireframe surfaces that color only the lines connecting the defining points. `surf` displays both the connecting lines and the faces of the surface in color.

Visualizing Functions of Two Variables

To display a function of two variables, $z = f(x,y)$,

- Generate $X$ and $Y$ matrices consisting of repeated rows and columns, respectively, over the domain of the function.
- Use $X$ and $Y$ to evaluate and graph the function.

The `meshgrid` function transforms the domain specified by a single vector or two vectors $x$ and $y$ into matrices $X$ and $Y$ for use in evaluating functions of two variables. The rows of $X$ are copies of the vector $x$ and the columns of $Y$ are copies of the vector $y$.

Example—Graphing the sinc Function

This example evaluates and graphs the two-dimensional sinc function, $\sin(r)/r$, between the $x$ and $y$ directions. $R$ is the distance from origin, which is at the center of the matrix. Adding `eps` (a MATLAB command that returns the smallest floating-point number on your system) avoids the indeterminate $0/0$ at the origin.

```matlab
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
mesh(X,Y,Z,'EdgeColor','black')
```
By default, MATLAB colors the mesh using the current colormap. However, this example uses a single-colored mesh by specifying the `EdgeColor` surface property. See the `surface` reference page for a list of all surface properties.

You can create a transparent mesh by disabling hidden line removal.

```plaintext
hidden off
```

See the `hidden` reference page for more information on this option.

**Example—Colored Surface Plots**

A surface plot is similar to a mesh plot except the rectangular faces of the surface are colored. The color of the faces is determined by the values of Z and the colormap (a colormap is an ordered list of colors). These statements graph the `sinc` function as a surface plot, select a colormap, and add a color bar to show the mapping of data to color.

```plaintext
surf(X,Y,Z)
colormap hsv
colorbar
```
See the colormap reference page for information on colormaps.

**Surface Plots with Lighting**

Lighting is the technique of illuminating an object with a directional light source. In certain cases, this technique can make subtle differences in surface shape easier to see. Lighting can also be used to add realism to three-dimensional graphs.

This example uses the same surface as the previous examples, but colors it red and removes the mesh lines. A light object is then added to the left of the “camera” (that is the location in space from where you are viewing the surface).
After adding the light and setting the lighting method to phong, use the `view` command to change the viewpoint so you are looking at the surface from a different point in space (an azimuth of -15 and an elevation of 65 degrees). Finally, zoom in on the surface using the toolbar zoom mode.

```matlab
surf(X,Y,Z,'FaceColor','red','EdgeColor','none');
camlight left; lighting phong
view(-15,65)
```
Images

Two-dimensional arrays can be displayed as images, where the array elements determine brightness or color of the images. For example, the statements

```
load durer
whos
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>648x509</td>
<td>2638656</td>
<td>double array</td>
</tr>
<tr>
<td>caption</td>
<td>2x28</td>
<td>112</td>
<td>char array</td>
</tr>
<tr>
<td>map</td>
<td>128x3</td>
<td>3072</td>
<td>double array</td>
</tr>
</tbody>
</table>

load the file `durer.mat`, adding three variables to the workspace. The matrix `X` is a 648-by-509 matrix and `map` is a 128-by-3 matrix that is the colormap for this image.

**Note** MAT-files, such as `durer.mat`, are binary files that can be created on one platform and later read by MATLAB on a different platform.

The elements of `X` are integers between 1 and 128, which serve as indices into the colormap, `map`. Then

```
image(X)
colormap(map)
axis image
```

reproduces Dürer’s etching shown at the beginning of this book. A high resolution scan of the magic square in the upper right corner is available in another file. Type

```
load detail
```

and then use the up arrow key on your keyboard to reexecute the `image`, `colormap`, and `axis` commands. The statement

```
colormap(hot)
```

adds some twentieth century colorization to the sixteenth century etching. The function `hot` generates a colormap containing shades of reds, oranges, and
yellows. Typically a given image matrix has a specific colormap associated with it. See the colormap reference page for a list of other predefined colormaps.
Printing Graphics

You can print a MATLAB figure directly on a printer connected to your computer or you can export the figure to one of the standard graphic file formats supported by MATLAB. There are two ways to print and export figures:

- Using the Print option under the File menu
- Using the print command

Printing from the Menu

There are four menu options under the File menu that pertain to printing:

- The Page Setup option displays a dialog box that enables you to adjust characteristics of the figure on the printed page.
- The Print Setup option displays a dialog box that sets printing defaults, but does not actually print the figure.
- The Print Preview option enables you to view the figure the way it will look on the printed page.
- The Print option displays a dialog box that lets you select standard printing options and print the figure.

Generally, use Print Preview to determine whether the printed output is what you want. If not, use the Page Setup dialog box to change the output settings. Select the Page Setup dialog box Help button to display information on how to set up the page.

Exporting Figure to Graphics Files

The Export option under the File menu enables you to export the figure to a variety of standard graphics file formats.

Using the Print Command

The print command provides more flexibility in the type of output sent to the printer and allows you to control printing from M-files. The result can be sent directly to your default printer or stored in a specified file. A wide variety of output formats, including TIFF, JPEG, and PostScript, is available.

For example, this statement saves the contents of the current figure window as color Encapsulated Level 2 PostScript in the file called magicsquare.eps. It
also includes a TIFF preview, which enables most word processors to display the picture

```
print -depsc2 -tiff magicsquare.eps
```

To save the same figure as a TIFF file with a resolution of 200 dpi, use the command

```
print -dtiff -r200 magicsquare.tiff
```

If you type `print` on the command line,

```
print
```

MATLAB prints the current figure on your default printer.
Handle Graphics

When you use a plotting command, MATLAB creates the graph using various graphics objects, such as lines, text, and surfaces (see “Graphics Objects” on page 4-26 for a complete list). All graphics objects have properties that control the appearance and behavior of the object. MATLAB enables you to query the value of each property and set the value of most properties.

Whenever MATLAB creates a graphics object, it assigns an identifier (called a handle) to the object. You can use this handle to access the object’s properties. Handle Graphics is useful if you want to

- Modify the appearance of graphs.
- Create custom plotting commands by writing M-files that create and manipulate objects directly.

Graphics Objects

Graphics objects are the basic elements used to display graphics and user interface elements. This table lists the graphics objects.

<table>
<thead>
<tr>
<th>Object</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root</td>
<td>Top of the hierarchy corresponding to the computer screen</td>
</tr>
<tr>
<td>Figure</td>
<td>Window used to display graphics and user interfaces</td>
</tr>
<tr>
<td>Axes</td>
<td>Axes for displaying graphs in a figure</td>
</tr>
<tr>
<td>Uicontrol</td>
<td>User interface control that executes a function in response to user interaction</td>
</tr>
<tr>
<td>Uimenu</td>
<td>User-defined figure window menu</td>
</tr>
<tr>
<td>Uicontextmenu</td>
<td>Pop-up menu invoked by right clicking on a graphics object</td>
</tr>
<tr>
<td>Image</td>
<td>Two-dimensional pixel-based picture</td>
</tr>
<tr>
<td>Light</td>
<td>Light sources that affect the coloring of patch and surface objects</td>
</tr>
</tbody>
</table>
Object Hierarchy
The objects are organized in a tree structured hierarchy reflecting their interdependence. For example, line objects require axes objects as a frame of reference. In turn, axes objects exist only within figure objects. This diagram illustrates the tree structure.

Creating Objects
Each object has an associated function that creates the object. These functions have the same name as the objects they create. For example, the text function creates text objects, the figure function creates figure objects, and so on. MATLAB high-level graphics functions (like plot and surf) call the
appropriate low-level function to draw their respective graphics. For more information about an object and a description of its properties, see the reference page for the object’s creation function. Object creation functions have the same name as the object. For example, the object creation function for axes objects is called axes.

**Commands for Working with Objects**

This table lists commands commonly used when working with objects.

<table>
<thead>
<tr>
<th>Function</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copyobj</td>
<td>Copy graphics object</td>
</tr>
<tr>
<td>delete</td>
<td>Delete an object</td>
</tr>
<tr>

**Setting Object Properties**

All object properties have default values. However, you may find it useful to change the settings of some properties to customize your graph. There are two ways to set object properties:

- Specify values for properties when you create the object.
- Set the property value on an object that already exists.

**Setting Properties from Plotting Commands**

You can specify object property values as arguments to object creation functions as well as with plotting function, such as `plot`, `mesh`, and `surf`. 
For example, plotting commands that create lines or surfaces enable you to specify property name/property value pairs as arguments. The command

\[
\text{plot}(x,y,\text{LineWidth'},1.5)\
\]

plots the data in the variables \(x\) and \(y\) using lines having a LineWidth property set to 1.5 points (one point = 1/72 inch). You can set any line object property this way.

**Setting Properties of Existing Objects**

To modify the property values of existing objects, you can use the `set` command or, if plot editing mode is enabled, the Property Editor. The Property Editor provides a graphical user interface to many object properties. This section describes how to use the set command. See “Using the Property Editor” on page 4-16 for more information.

Many plotting commands can return the handles of the objects created so you can modify the objects using the `set` command. For example, these statements plot a five-by-five matrix (creating five lines, one per column) and then set the Marker to a square and the MarkerFaceColor to green.

```
 h = plot(magic(5));
 set(h,'Marker','s',MarkerFaceColor','g')
```

In this case, \(h\) is a vector containing five handles, one for each of the five lines in the plot. The `set` statement sets the Marker and MarkerFaceColor properties of all lines to the same values.

**Setting Multiple Property Values**

If you want to set the properties of each line to a different value, you can use cell arrays to store all the data and pass it to the `set` command. For example, create a plot and save the line handles.

```
 h = plot(magic(5));
```

Suppose you want to add different markers to each line and color the marker’s face color to the same color as the line. You need to define two cell arrays – one containing the property names and the other containing the desired values of the properties.
The prop_name cell array contains two elements.

```matlab
prop_name(1) = {'Marker'};
prop_name(2) = {'MarkerFaceColor'};
```

The prop_values cell array contains 10 values; five values for the Marker property and five values for the MarkerFaceColor property. Notice that prop_values is a two-dimensional cell array. The first dimension indicates which handle in h the values apply to and the second dimension indicates which property the value is assigned to.

```matlab
prop_values(1,1) = {'s'};
prop_values(1,2) = {get(h(1),'Color')};
prop_values(2,1) = {'d'};
prop_values(2,2) = {get(h(2),'Color')};
prop_values(3,1) = {'o'};
prop_values(3,2) = {get(h(3),'Color')};
prop_values(4,1) = {'p'};
prop_values(4,2) = {get(h(4),'Color')};
prop_values(5,1) = {'h'};
prop_values(5,2) = {get(h(5),'Color')};
```

The MarkerFaceColor is always assigned the value of the corresponding line’s color (obtained by getting the line’s Color property with the get command).

After defining the cell arrays, call set to specify the new property values.

```matlab
set(h,prop_name,prop_values)
```
Finding the Handles of Existing Objects

The `findobj` command enables you to obtain the handles of graphics objects by searching for objects with particular property values. With `findobj` you can specify the value of any combination of properties, which makes it easy to pick one object out of many. For example, you may want to find the blue line with square marker having blue face color.

You can also specify which figures or axes to search, if there is more than one. The following sections provide examples illustrating how to use `findobj`.

Finding All Objects of a Certain Type

Since all objects have a `Type` property that identifies the type of object, you can find the handles of all occurrences of a particular type of object. For example,

```matlab
h = findobj('Type','line');
```

finds the handles of all line objects.
Finding Objects with a Particular Property
You can specify multiple properties to narrow the search. For example,

```matlab
h = findobj('Type','line','Color','r','LineStyle',':');
```

finds the handles of all red, dotted lines.

Limiting the Scope of the Search
You can specify the starting point in the object hierarchy by passing the handle of the starting figure or axes as the first argument. For example,

```matlab
h = findobj(gca,'Type','text','String','\pi/2');
```

finds the string $\pi/2$ only within the current axes.

Using `findobj` as an Argument
Since `findobj` returns the handles it finds, you can use it in place of the handle argument. For example,

```matlab
set(findobj('Type','line','Color','red'),'LineStyle',':')
```

finds all red lines and sets their line style to dotted.
Graphics User Interfaces

Here is a simple example illustrating how to use Handle Graphics to build user interfaces. The statement

```matlab
b = uicontrol('Style','pushbutton', ... \
    'Units','normalized', ... \
    'Position',[.5 .5 .2 .1], ... \
    'String','click here');
```

creates a push button in the center of a figure window and returns a handle to the new object. But, so far, clicking the button does nothing. The statement

```matlab
s = 'set(b,''Position'',[.8*rand .9*rand .2 .1])';
```

creates a string containing a command that alters the push button’s position. Repeated execution of

```matlab
eval(s)
```

moves the button to random positions. Finally,

```matlab
set(b,'Callback',s)
```

installs s as the button’s callback action, so every time you click the button, it moves to a new position.

Graphical User Interface Design Tools
MATLAB provides GUI Design Environment (GUIDE) tools that simplify the creation of graphical user interfaces. To display the GUIDE Layout Editor, issue the `guide` command.
Animations

MATLAB provides two ways of generating moving, animated graphics:

- “Erase Mode Method” on page 4-34—Continually erase and then redraw the objects on the screen, making incremental changes with each redraw.
- “Creating Movies” on page 4-35—Save a number of different pictures and then play them back as a movie.

Erase Mode Method

Using the EraseMode property is appropriate for long sequences of simple plots where the change from frame to frame is minimal. Here is an example showing simulated Brownian motion. Specify a number of points, such as

\[ n = 20 \]

and a temperature or velocity, such as

\[ s = .02 \]

The best values for these two parameters depend upon the speed of your particular computer. Generate \( n \) random points with \((x,y)\) coordinates between \(-\frac{1}{2}\) and \(+\frac{1}{2}\).

\[
\begin{align*}
x &= \text{rand}(n,1) - 0.5; \\
y &= \text{rand}(n,1) - 0.5;
\end{align*}
\]

Plot the points in a square with sides at -1 and +1. Save the handle for the vector of points and set its EraseMode to xor. This tells the MATLAB graphics system not to redraw the entire plot when the coordinates of one point are changed, but to restore the background color in the vicinity of the point using an “exclusive or” operation.

\[
\begin{align*}
h &= \text{plot}(x,y,'.'); \\
axis([-1 1 -1 1]) \\
axis square \\
grid off \\
set(h,'EraseMode','xor','MarkerSize',18)
\end{align*}
\]

Now begin the animation. Here is an infinite while loop, which you can eventually exit by typing Ctrl+c. Each time through the loop, add a small amount of normally distributed random noise to the coordinates of the points.

\[
\begin{align*}
x &= \text{rand}(n,1) - 0.5; \\
y &= \text{rand}(n,1) - 0.5;
\end{align*}
\]

Plot the points in a square with sides at -1 and +1. Save the handle for the vector of points and set its EraseMode to xor. This tells the MATLAB graphics system not to redraw the entire plot when the coordinates of one point are changed, but to restore the background color in the vicinity of the point using an “exclusive or” operation.

\[
\begin{align*}
h &= \text{plot}(x,y,'.'); \\
axis([-1 1 -1 1]) \\
axis square \\
grid off \\
set(h,'EraseMode','xor','MarkerSize',18)
\end{align*}
\]

Now begin the animation. Here is an infinite while loop, which you can eventually exit by typing Ctrl+c. Each time through the loop, add a small amount of normally distributed random noise to the coordinates of the points.

\[
\begin{align*}
x &= \text{rand}(n,1) - 0.5; \\
y &= \text{rand}(n,1) - 0.5;
\end{align*}
\]

Plot the points in a square with sides at -1 and +1. Save the handle for the vector of points and set its EraseMode to xor. This tells the MATLAB graphics system not to redraw the entire plot when the coordinates of one point are changed, but to restore the background color in the vicinity of the point using an “exclusive or” operation.
Then, instead of creating an entirely new plot, simply change the XData and YData properties of the original plot.

```matlab
while 1
drawnow
    x = x + s*randn(n,1);
    y = y + s*randn(n,1);
    set(h,'XData',x,'YData',y)
end
```

How long does it take for one of the points to get outside the square? How long before all the points are outside the square?

Creating Movies

If you increase the number of points in the Brownian motion example to something like \( n = 300 \) and \( s = 0.02 \), the motion is no longer very fluid; it takes too much time to draw each time step. It becomes more effective to save a predetermined number of frames as bitmaps and to play them back as a movie.
First, decide on the number of frames, say
\[ nframes = 50; \]

Next, set up the first plot as before, except using the default EraseMode (normal).
\[ x = \text{rand}(n,1) - 0.5; \]
\[ y = \text{rand}(n,1) - 0.5; \]
\[ h = \text{plot}(x,y, \text{'.');} \]
\[ \text{set}(h,'\text{MarkerSize}',18); \]
\[ \text{axis([-1 1 -1 1])} \]
\[ \text{axis square} \]
\[ \text{grid off} \]

Generate the movie and use getframe to capture each frame.
\[ \text{for } k = 1:nframes \]
\[ \text{x = x + s*randn(n,1);} \]
\[ \text{y = y + s*randn(n,1);} \]
\[ \text{set}(h,'\text{XData}',x,'\text{YData}',y) \]
\[ \text{M(k) = getframe;} \]
\[ \text{end} \]

Finally, play the movie 30 times.
\[ \text{movie(M,30)} \]
Programming with MATLAB

Flow Control (p. 5-2) Use flow control constructs including if, switch and case, for, while, continue, and break.

Other Data Structures (p. 5-7) Work with multidimensional arrays, cell arrays, character and text data, and structures.

Scripts and Functions (p. 5-17) Write scripts and functions, use global variables, pass string arguments to functions, use eval to evaluate text expressions, vectorize code, preallocate arrays, reference functions using handles, and use function that operate on functions.

Demonstration Programs Included with MATLAB (p. 5-28) View and run demos.
Flow Control

MATLAB has several flow control constructs:

- “if” on page 5-2
- “switch and case” on page 5-3
- “for” on page 5-4
- while on page 5-5
- “continue” on page 5-5
- “break” on page 5-6

if

The if statement evaluates a logical expression and executes a group of statements when the expression is true. The optional elseif and else keywords provide for the execution of alternate groups of statements. An end keyword, which matches the if, terminates the last group of statements. The groups of statements are delineated by the four keywords—no braces or brackets are involved.

The MATLAB algorithm for generating a magic square of order \( n \) involves three different cases: when \( n \) is odd, when \( n \) is even but not divisible by 4, or when \( n \) is divisible by 4. This is described by

```matlab
if rem(n,2) ~= 0
    M = odd_magic(n)
elseif rem(n,4) ~= 0
    M = single_even_magic(n)
else
    M = double_even_magic(n)
end
```

In this example, the three cases are mutually exclusive, but if they weren’t, the first true condition would be executed.

It is important to understand how relational operators and if statements work with matrices. When you want to check for equality between two variables, you might use

```matlab
if A == B, ...
```
This is legal MATLAB code, and does what you expect when A and B are scalars. But when A and B are matrices, 
A == B does not test if they are equal, it tests where they are equal; the result is another matrix of 0’s and 1’s showing 
element-by-element equality. In fact, if A and B are not the same size, then A == B is an error.

The proper way to check for equality between two variables is to use the isequal function,

    if isequal(A,B), ...

Here is another example to emphasize this point. If A and B are scalars, the following program will never reach the unexpected situation. But for most pairs of matrices, including our magic squares with interchanged columns, none of the matrix conditions A > B, A < B or A == B is true for all elements and so the else clause is executed.

    if A > B
        'greater'
    elseif A < B
        'less'
    elseif A == B
        'equal'
    else
        error('Unexpected situation')
    end

Several functions are helpful for reducing the results of matrix comparisons to scalar conditions for use with if, including

    isequal
    isempty
    all
    any

**switch and case**

The switch statement executes groups of statements based on the value of a variable or expression. The keywords case and otherwise delineate the groups. Only the first matching case is executed. There must always be an end to match the switch.
The logic of the magic squares algorithm can also be described by

\[
\text{switch } (\text{rem}(n,4)==0) + (\text{rem}(n,2)==0) \\
\quad \text{case 0} \\
\quad \quad M = \text{odd_magic}(n) \\
\quad \text{case 1} \\
\quad \quad M = \text{single_even_magic}(n) \\
\quad \text{case 2} \\
\quad \quad M = \text{double_even_magic}(n) \\
\quad \text{otherwise} \\
\quad \quad \text{error('This is impossible')} \\
\text{end}
\]

**Note**  Unlike the C language switch statement, MATLAB switch does not fall through. If the first case statement is *true*, the other case statements do not execute. So, break statements are not required.

**for**

The `for` loop repeats a group of statements a fixed, predetermined number of times. A matching `end` delineates the statements.

```
for n = 3:32
    r(n) = rank(magic(n));
end
r
```

The semicolon terminating the inner statement suppresses repeated printing, and the `r` after the loop displays the final result.

It is a good idea to indent the loops for readability, especially when they are nested.

```
for i = 1:m
    for j = 1:n
        H(i,j) = 1/(i+j);
    end
end
```

5-4
The while loop repeats a group of statements an indefinite number of times under control of a logical condition. A matching end delineates the statements.

Here is a complete program, illustrating while, if, else, and end, that uses interval bisection to find a zero of a polynomial.

```plaintext
a = 0; fa = -Inf;
b = 3; fb = Inf;
while b-a > eps*b
    x = (a+b)/2;
    fx = x^3-2*x-5;
    if sign(fx) == sign(fa)
        a = x; fa = fx;
    else
        b = x; fb = fx;
    end
end
x
```

The result is a root of the polynomial $x^3 - 2x - 5$, namely

$$x = 2.09455148154233$$

The cautions involving matrix comparisons that are discussed in the section on the if statement also apply to the while statement.

The continue statement passes control to the next iteration of the for or while loop in which it appears, skipping any remaining statements in the body of the loop. In nested loops, continue passes control to the next iteration of the for or while loop enclosing it.
The example below shows a continue loop that counts the lines of code in the file, magic.m, skipping all blank lines and comments. A continue statement is used to advance to the next line in magic.m without incrementing the count whenever a blank line or comment line is encountered.

```matlab
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) | strncmp(line,'%',1)
        continue
    end
    count = count + 1;
end
disp(sprintf('%d lines',count));
```

**break**

The break statement lets you exit early from a for or while loop. In nested loops, break exits from the innermost loop only.

Here is an improvement on the example from the previous section. Why is this use of break a good idea?

```matlab
a = 0; fa = -Inf;
b = 3; fb = Inf;
while b-a > eps*b
    x = (a+b)/2;
    fx = x^3-2*x-5;
    if fx == 0
        break
    elseif sign(fx) == sign(fa)
        a = x; fa = fx;
    else
        b = x; fb = fx;
    end
end
x
```
Other Data Structures

This section introduces you to some other data structures in MATLAB, including

- “Multidimensional Arrays” on page 5-7
- “Cell Arrays” on page 5-9
- “Characters and Text” on page 5-11
- “Structures” on page 5-14

Multidimensional Arrays

Multidimensional arrays in MATLAB are arrays with more than two subscripts. They can be created by calling zeros, ones, rand, or randn with more than two arguments. For example,

\[
R = \text{randn}(3,4,5);
\]

creates a 3-by-4-by-5 array with a total of 3x4x5 = 60 normally distributed random elements.

A three-dimensional array might represent three-dimensional physical data, say the temperature in a room, sampled on a rectangular grid. Or, it might represent a sequence of matrices, \(A^{(k)}\), or samples of a time-dependent matrix, \(A(t)\). In these latter cases, the \((i, j)\)th element of the \(k\)th matrix, or the \(t_k\)th matrix, is denoted by \(A(i, j, k)\).

MATLAB and Dürer’s versions of the magic square of order 4 differ by an interchange of two columns. Many different magic squares can be generated by interchanging columns. The statement

\[
p = \text{perms}(1:4);
\]

generates the \(4! = 24\) permutations of \(1:4\). The \(k\)th permutation is the row vector, \(p(k,:)\). Then

\[
A = \text{magic}(4);
M = \text{zeros}(4,4,24);
\text{for } k = 1:24
    M(:,:,k) = A(:,p(k,:));
\text{end}
\]
stores the sequence of 24 magic squares in a three-dimensional array, \( M \). The size of \( M \) is

\[
\text{size}(M)
\]

\[
\text{ans} = \\
4 \\
4 \\
24
\]

It turns out that the third matrix in the sequence is Dürer’s.

\[
M(:,:,3)
\]

\[
\begin{array}{cccc}
16 & 3 & 2 & 13 \\
5 & 11 & 10 & 8 \\
9 & 7 & 6 & 12 \\
4 & 14 & 15 & 1 \\
\end{array}
\]

The statement

\[
\text{sum}(M,d)
\]

computes sums by varying the \( d \)th subscript. So

\[
\text{sum}(M,1)
\]
is a 1-by-4-by-24 array containing 24 copies of the row vector
\[
\begin{array}{cccc}
34 & 34 & 34 & 34 \\
\end{array}
\]
and
\[
\text{sum}(M,2)
\]
is a 4-by-1-by-24 array containing 24 copies of the column vector
\[
\begin{array}{cccc}
34 \\
34 \\
34 \\
34 \\
\end{array}
\]
Finally,
\[
S = \text{sum}(M,3)
\]
adds the 24 matrices in the sequence. The result has size 4-by-4-by-1, so it looks like a 4-by-4 array.
\[
S =
\begin{bmatrix}
204 & 204 & 204 & 204 \\
204 & 204 & 204 & 204 \\
204 & 204 & 204 & 204 \\
204 & 204 & 204 & 204 \\
\end{bmatrix}
\]

**Cell Arrays**

Cell arrays in MATLAB are multidimensional arrays whose elements are copies of other arrays. A cell array of empty matrices can be created with the `cell` function. But, more often, cell arrays are created by enclosing a miscellaneous collection of things in curly braces, `{}`. The curly braces are also used with subscripts to access the contents of various cells. For example,
\[
C = \{A \ \text{sum}(A) \ \text{prod(prod(A))}\}
\]
produces a 1-by-3 cell array. The three cells contain the magic square, the row vector of column sums, and the product of all its elements. When `C` is displayed, you see
\[
C =
\begin{bmatrix}
\text{4x4 double} & \text{1x4 double} & 20922789888000
\end{bmatrix}
\]
This is because the first two cells are too large to print in this limited space, but the third cell contains only a single number, 16!, so there is room to print it.

Here are two important points to remember. First, to retrieve the contents of one of the cells, use subscripts in curly braces. For example, \( C\{1\} \) retrieves the magic square and \( C\{3\} \) is 16!. Second, cell arrays contain copies of other arrays, not pointers to those arrays. If you subsequently change \( A \), nothing happens to \( C \).

Three-dimensional arrays can be used to store a sequence of matrices of the same size. Cell arrays can be used to store a sequence of matrices of different sizes. For example,

\[
M = \text{cell}(8,1); \\
\text{for } n = 1:8 \\
\quad M\{n\} = \text{magic}(n); \\
\text{end} \\
M
\]

produces a sequence of magic squares of different order.

\[
M = \\
\begin{bmatrix}
1 \\
\text{2x2 double} \\
\text{3x3 double} \\
\text{4x4 double} \\
\text{5x5 double} \\
\text{6x6 double} \\
\text{7x7 double} \\
\text{8x8 double}
\end{bmatrix}
\]
You can retrieve our old friend with

\[ M(4) \]

**Characters and Text**

Enter text into MATLAB using single quotes. For example,

\[ s = 'Hello' \]

The result is not the same kind of numeric matrix or array we have been dealing with up to now. It is a 1-by-5 character array.
Internally, the characters are stored as numbers, but not in floating-point format. The statement

```matlab
a = double(s)
```

converts the character array to a numeric matrix containing floating-point representations of the ASCII codes for each character. The result is

```
a = 
   72    101    108    108    111
```

The statement

```matlab
s = char(a)
```

reverses the conversion.

Converting numbers to characters makes it possible to investigate the various fonts available on your computer. The printable characters in the basic ASCII character set are represented by the integers 32:127. (The integers less than 32 represent nonprintable control characters.) These integers are arranged in an appropriate 6-by-16 array with

```matlab
F = reshape(32:127,16,6)';
```

The printable characters in the extended ASCII character set are represented by F+128. When these integers are interpreted as characters, the result depends on the font currently being used. Type the statements

```matlab
char(F)
char(F+128)
```

and then vary the font being used for the MATLAB Command Window. Select Preferences from the File menu. Be sure to try the Symbol and Wingdings fonts, if you have them on your computer. Here is one example of the kind of output you might obtain.

```
! "#$%&'()*/+,-./ 0123456789:<=>? @ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_`
'abcdefghijklmno
pqrstuvwxyz{|}~-
c£§ ¶ fi' ·£f```

5-12
Concatenation with square brackets joins text variables together into larger strings. The statement

```matlab
h = [s, ' world']
```

joins the strings horizontally and produces

```matlab
h =
    Hello world
```

The statement

```matlab
v = [s; 'world']
```

joins the strings vertically and produces

```matlab
v =
    Hello
    world
```

Note that a blank has to be inserted before the ‘w’ in h and that both words in v have to have the same length. The resulting arrays are both character arrays; h is 1-by-11 and v is 2-by-5.

To manipulate a body of text containing lines of different lengths, you have two choices—a padded character array or a cell array of strings. The `char` function accepts any number of lines, adds blanks to each line to make them all the same length, and forms a character array with each line in a separate row. For example,

```matlab
S = char('A','rolling','stone','gathers','momentum.')
```

produces a 5-by-9 character array.

```matlab
S =
A
rolling
stone
gathers
momentum.
```
There are enough blanks in each of the first four rows of S to make all the rows the same length. Alternatively, you can store the text in a cell array. For example,

\[ C = \{ 'A'; 'rolling'; 'stone'; 'gathers'; 'momentum.' \} \]

is a 5-by-1 cell array.

\[ C = \]

\[ 'A'

\[ 'rolling'

\[ 'stone'

\[ 'gathers'

\[ 'momentum.' \]

You can convert a padded character array to a cell array of strings with

\[ C = \text{cellstr}(S) \]

and reverse the process with

\[ S = \text{char}(C) \]

**Structures**

Structures are multidimensional MATLAB arrays with elements accessed by textual field designators. For example,

\[ S\text{.name} = 'Ed Plum'; \]
\[ S\text{.score} = 83; \]
\[ S\text{.grade} = 'B+' \]

creates a scalar structure with three fields.

\[ S = \]

\[ \text{name: 'Ed Plum'} \]
\[ \text{score: 83} \]
\[ \text{grade: 'B+'} \]
Like everything else in MATLAB, structures are arrays, so you can insert additional elements. In this case, each element of the array is a structure with several fields. The fields can be added one at a time,

\begin{verbatim}
S(2).name = 'Toni Miller';
S(2).score = 91;
S(2).grade = 'A-';
\end{verbatim}

or an entire element can be added with a single statement.

\begin{verbatim}
S(3) = struct('name','Jerry Garcia','score',70,'grade','C')
\end{verbatim}

Now the structure is large enough that only a summary is printed.

\begin{verbatim}
S =
1x3 struct array with fields:
    name
    score
    grade
\end{verbatim}

There are several ways to reassemble the various fields into other MATLAB arrays. They are all based on the notation of a comma-separated list. If you type

\begin{verbatim}
S.score
\end{verbatim}

it is the same as typing

\begin{verbatim}
S(1).score, S(2).score, S(3).score
\end{verbatim}

This is a comma-separated list. Without any other punctuation, it is not very useful. It assigns the three scores, one at a time, to the default variable ans and dutifully prints out the result of each assignment. But when you enclose the expression in square brackets,

\begin{verbatim}
[S.score]
\end{verbatim}

it is the same as

\begin{verbatim}
[S(1).score, S(2).score, S(3).score]
\end{verbatim}

which produces a numeric row vector containing all the scores.

\begin{verbatim}
ans =
     83    91    70
\end{verbatim}
Similarly, typing

```matlab
S.name
```

just assigns the names, one at a time, to ans. But enclosing the expression in curly braces,

```matlab
{S.name}
```

creates a 1-by-3 cell array containing the three names.

```matlab
ans =
    'Ed Plum'    'Toni Miller'    'Jerry Garcia'
```

And

```matlab
char(S.name)
```

calls the `char` function with three arguments to create a character array from the name fields,

```matlab
ans =
    Ed Plum
    Toni Miller
    Jerry Garcia
```
Scripts and Functions

Topics covered in this section are

- “Scripts” on page 5-18
- “Functions” on page 5-19
- “Global Variables” on page 5-21
- “Passing String Arguments to Functions” on page 5-21
- “The eval Function” on page 5-23
- “Vectorization” on page 5-23
- “Preallocation” on page 5-24
- “Function Handles” on page 5-24
- “Function Functions” on page 5-25

MATLAB is a powerful programming language as well as an interactive computational environment. Files that contain code in the MATLAB language are called M-files. You create M-files using a text editor, then use them as you would any other MATLAB function or command.

There are two kinds of M-files:

- Scripts, which do not accept input arguments or return output arguments. They operate on data in the workspace.
- Functions, which can accept input arguments and return output arguments. Internal variables are local to the function.

If you’re a new MATLAB programmer, just create the M-files that you want to try out in the current directory. As you develop more of your own M-files, you will want to organize them into other directories and personal toolboxes that you can add to your MATLAB search path.

If you duplicate function names, MATLAB executes the one that occurs first in the search path.

To view the contents of an M-file, for example, myfunction.m, use

    type myfunction
**Scripts**

When you invoke a script, MATLAB simply executes the commands found in the file. Scripts can operate on existing data in the workspace, or they can create new data on which to operate. Although scripts do not return output arguments, any variables that they create remain in the workspace, to be used in subsequent computations. In addition, scripts can produce graphical output using functions like `plot`.

For example, create a file called `magicrank.m` that contains these MATLAB commands.

```matlab
% Investigate the rank of magic squares
r = zeros(1,32);
for n = 3:32
    r(n) = rank(magic(n));
end
r
bar(r)
```

Typing the statement

```
magicrank
```

causes MATLAB to execute the commands, compute the rank of the first 30 magic squares, and plot a bar graph of the result. After execution of the file is complete, the variables `n` and `r` remain in the workspace.
Functions

Functions are M-files that can accept input arguments and return output arguments. The name of the M-file and of the function should be the same. Functions operate on variables within their own workspace, separate from the workspace you access at the MATLAB command prompt.

A good example is provided by rank. The M-file rank.m is available in the directory

```
toolbox/matlab/matfun
```

You can see the file with

```
type rank
```
Here is the file.

```matlab
function r = rank(A,tol)
% RANK Matrix rank.
% RANK(A) provides an estimate of the number of linearly
% independent rows or columns of a matrix A.
% RANK(A,tol) is the number of singular values of A
% that are larger than tol.
% RANK(A) uses the default tol = max(size(A)) * norm(A) * eps.

s = svd(A);
if nargin==1
    tol = max(size(A))' * max(s) * eps;
end
r = sum(s > tol);
```

The first line of a function M-file starts with the keyword `function`. It gives the function name and order of arguments. In this case, there are up to two input arguments and one output argument.

The next several lines, up to the first blank or executable line, are comment lines that provide the help text. These lines are printed when you type

```
help rank
```

The first line of the help text is the H1 line, which MATLAB displays when you use the `lookfor` command or request `help` on a directory.

The rest of the file is the executable MATLAB code defining the function. The variable `s` introduced in the body of the function, as well as the variables on the first line, `r`, `A` and `tol`, are all `local` to the function; they are separate from any variables in the MATLAB workspace.

This example illustrates one aspect of MATLAB functions that is not ordinarily found in other programming languages – a variable number of arguments. The `rank` function can be used in several different ways.

```matlab
rank(A)
r = rank(A)
r = rank(A,1.e-6)
```

Many M-files work this way. If no output argument is supplied, the result is stored in `ans`. If the second input argument is not supplied, the function
computes a default value. Within the body of the function, two quantities named nargin and nargout are available which tell you the number of input and output arguments involved in each particular use of the function. The rank function uses nargin, but does not need to use nargout.

**Global Variables**
If you want more than one function to share a single copy of a variable, simply declare the variable as global in all the functions. Do the same thing at the command line if you want the base workspace to access the variable. The global declaration must occur before the variable is actually used in a function. Although it is not required, using capital letters for the names of global variables helps distinguish them from other variables. For example, create an M-file called falling.m.

```matlab
function h = falling(t)
global GRAVITY
h = 1/2*GRAVITY*t.^2;
```

Then interactively enter the statements

```matlab
global GRAVITY
GRAVITY = 32;
y = falling((0:.1:5)');
```

The two global statements make the value assigned to GRAVITY at the command prompt available inside the function. You can then modify GRAVITY interactively and obtain new solutions without editing any files.

**Passing String Arguments to Functions**
You can write MATLAB functions that accept string arguments without the parentheses and quotes. That is, MATLAB interprets

```matlab
foo a b c
```

as

```matlab
foo('a','b','c')
```

However, when using the unquoted form, MATLAB cannot return output arguments. For example,

```matlab
legend apples oranges
```
creates a legend on a plot using the strings apples and oranges as labels. If you want the `legend` command to return its output arguments, then you must use the quoted form.

```matlab
[legh, objh] = legend('apples', 'oranges');
```

In addition, you cannot use the unquoted form if any of the arguments is not a string.

**Constructing String Arguments in Code**

The quoted form enables you to construct string arguments within the code. The following example processes multiple data files, August1.dat, August2.dat, and so on. It uses the function `int2str`, which converts an integer to a character, to build the filename.

```matlab
for d = 1:31
    s = ['August' int2str(d) '.dat'];
    load(s)
    % Code to process the contents of the d-th file
end
```

**A Cautionary Note**

While the unquoted syntax is convenient, it can be used incorrectly without causing MATLAB to generate an error. For example, given a matrix A,

```matlab
A =
    0  -6  -1
   6   2 -16
  -5  20 -10
```

The `eig` command returns the eigenvalues of A.

```matlab
eig(A)
ans =
- 3.0710
-2.4645+17.6008i
-2.4645-17.6008i
```
The following statement is not allowed because A is not a string; however, MATLAB does not generate an error.

\[
\text{eig A}
\]
\[
\text{ans =}
\]
\[
65
\]

MATLAB actually takes the eigenvalues of ASCII numeric equivalent of the letter A (which is the number 65).

**The eval Function**

The `eval` function works with text variables to implement a powerful text macro facility. The expression or statement

\[
\text{eval(s)}
\]

uses the MATLAB interpreter to evaluate the expression or execute the statement contained in the text string `s`.

The example of the previous section could also be done with the following code, although this would be somewhat less efficient because it involves the full interpreter, not just a function call.

```
for d = 1:31
    s = ['load August' int2str(d) '.dat'];
    eval(s)
    % Process the contents of the d-th file
end
```

**Vectorization**

To obtain the most speed out of MATLAB, it’s important to vectorize the algorithms in your M-files. Where other programming languages might use for or do loops, MATLAB can use vector or matrix operations. A simple example involves creating a table of logarithms.

```
x = .01;
for k = 1:1001
    y(k) = log10(x);
    x = x + .01;
end
```
A vectorized version of the same code is
\[
\begin{align*}
x &= .01:.01:10; \\
y &= \log10(x);
\end{align*}
\]
For more complicated code, vectorization options are not always so obvious. When speed is important, however, you should always look for ways to vectorize your algorithms.

**Preallocation**

If you can't vectorize a piece of code, you can make your for loops go faster by preallocating any vectors or arrays in which output results are stored. For example, this code uses the function zeros to preallocate the vector created in the for loop. This makes the for loop execute significantly faster.

\[
r = \text{zeros}(32,1); \\
\text{for } n = 1:32 \\
\quad r(n) = \text{rank}(	ext{magic}(n)); \\
\text{end}
\]

Without the preallocation in the previous example, the MATLAB interpreter enlarges the \(r\) vector by one element each time through the loop. Vector preallocation eliminates this step and results in faster execution.

**Function Handles**

You can create a handle to any MATLAB function and then use that handle as a means of referencing the function. A function handle is typically passed in an argument list to other functions, which can then execute, or evaluate, the function using the handle.

Construct a function handle in MATLAB using the at sign, @, before the function name. The following example creates a function handle for the \(\sin\) function and assigns it to the variable \(fhandle\).

\[
fhandle = @\sin;
\]

Evaluate a function handle using the MATLAB feval function. The function plot_fhandle, shown below, receives a function handle and data, and then performs an evaluation of the function handle on that data using feval.

\[
\begin{align*}
\text{function } x &= \text{plot}_\text{fhandle}(fhandle, \text{data}) \\
\text{plot}(	ext{data, feval}(fhandle, \text{data}))
\end{align*}
\]
When you call `plot_fhandle` with a handle to the `sin` function and the argument shown below, the resulting evaluation produces a sine wave plot.

```matlab
plot_fhandle(@sin, -pi:0.01:pi)
```

**Function Functions**

A class of functions called “function functions” works with nonlinear functions of a scalar variable. That is, one function works on another function. The function functions include:

- Zero finding
- Optimization
- Quadrature
- Ordinary differential equations

MATLAB represents the nonlinear function by a function M-file. For example, here is a simplified version of the function `humps` from the `matlab/demos` directory.

```matlab
function y = humps(x)
    y = 1./((x-.3).^2 + .01) + 1./((x-.9).^2 + .04) - 6;
```

Evaluate this function at a set of points in the interval $0 \leq x \leq 1$ with

```matlab
x = 0:.002:1;
y = humps(x);
```

Then plot the function with

```matlab
plot(x,y)
```
The graph shows that the function has a local minimum near $x = 0.6$. The function `fminsearch` finds the *minimizer*, the value of $x$ where the function takes on this minimum. The first argument to `fminsearch` is a function handle to the function being minimized and the second argument is a rough guess at the location of the minimum.

```matlab
p = fminsearch(@humps,.5)
p =
  0.6370
```

To evaluate the function at the minimizer,

```matlab
humps(p)
```

```matlab
ans =
  11.2528
```

Numerical analysts use the terms *quadrature* and *integration* to distinguish between numerical approximation of definite integrals and numerical
integration of ordinary differential equations. MATLAB quadrature routines are quad and quadl. The statement

\[ Q = \text{quadl}(@\text{humps},0,1) \]

computes the area under the curve in the graph and produces

\[ Q = 29.8583 \]

Finally, the graph shows that the function is never zero on this interval. So, if you search for a zero with

\[ z = \text{fzero}(@\text{humps},.5) \]

you will find one outside the interval

\[ z = -0.1316 \]
Demonstration Programs Included with MATLAB

MATLAB includes many demonstration programs that highlight various features and functions. For a complete list of the demos, type

demo

A list of demos for the products you have installed appears in the Demos tab of the Help browser. Select the product, category, and demo. Information to run the demo and view the source code appears in the display pane.

In addition to the demos listed below, the Demos tab includes playback demos which illustrate how certain graphical user interfaces work.

Some demos listed here are not directly available via the Help browser Demos tab. The description includes “(command line)”. To run these demos, type the demo name at the command line.

---

Note Many of the demonstrations use multiple windows and require you to press a key in the MATLAB Command Window to continue through the demonstration.

---

The following tables list the current demonstration programs that are available, organized into these categories:

- “Matrix Demonstration Programs” on page 5-29
- “Numeric Demonstration Programs” on page 5-30
- “Graphics Demonstration Programs” on page 5-31
- “Language Demonstration Programs” on page 5-32
- “Differential Equations Demonstration Programs” on page 5-33
- “Gallery Demonstration Programs” on page 5-34
- “Miscellaneous Demonstration Programs” on page 5-36
### Matrix Demonstration Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Description</th>

legend, adding to plot 4-3
library
  mathematical function 1-3
lighting 4-20
limits, axes 4-10
line continuation 3-30
line styles of plots 4-4
load 3-15
loading arrays 3-15
local variables 5-20
log of functions used 2-6
logical vectors 3-26

M
magic 3-8
magic square 3-4
markers 4-5
MAT-file 4-22
mathematical function library 1-3
mathematical functions
  listing advanced 3-11
  listing elementary 3-11
  listing matrix 3-11
MATLAB
  Application Program Interface 1-3
  history 1-2
  language 1-3
  mathematical function library 1-3
  overview 1-2
matrices 3-18
  creating 3-14
  entering 3-3
matrix 3-2
  antidiagonal 3-6
  determinant 3-19
  main diagonal 3-5
  singular 3-19
  swapping columns 3-8
  symmetric 3-18
  transpose 3-4
matrix multiplication 3-19
mesh plot 4-18
M-file 1-2, 3-15, 5-17
  creating 5-17
  for creating arrays 3-15
  function 5-17, 5-19
  script 5-17
M-files 2-14
Microsoft Word and access to MATLAB 2-16
movies 4-35
multidimensional arrays 5-7
multiple data sets, plotting 4-3
multiple plots per figure 4-9
multivariate data, organizing 3-24

N
newsgroup for MATLAB users 2-10
Notebook 2-16
numbers 3-10
  floating-point 3-11

O
object properties 4-28
objects
  finding handles 4-31
  graphics 4-26
online help, viewing 2-7
operator 3-11
  colon 3-7
output
  controlling format 3-28
  suppressing 3-30
overlaying plots 4-7

P
path 2-11
plot 4-2
plot editing mode
  overview 4-15
plots
  editing 4-14
plotting
  adding legend 4-3
  adding plots 4-7
  annotating 4-14
  basic 4-2
  complex data 4-6
  complex numbers 4-6
  contours 4-8
  line colors 4-4
  line styles 4-4
